# EMISSIONS 2018 OECD average: 2018 Austrian average: Austrian target: net zero GHG emissions by 2040

# Large regions (TL2)

Figure 1. Estimated regional greenhouse gas emissions per capita

Tons CO<sub>2</sub> equivalent (tCO<sub>2</sub>e), large regions (TL2), 2018

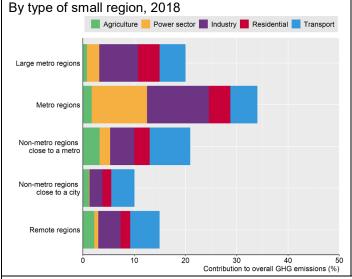

Greenhouse gas (GHG) emissions per capita generated in the majority of Austrian large regions are below 10 tCO<sub>2</sub>e per capita. Only Upper Austria and Styria have higher emissions per capita than the OECD average of 11.5 tCO<sub>2</sub>e.

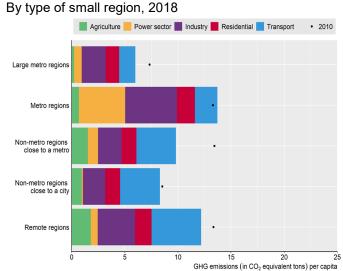

Estimated emissions per capita produced in Upper Austria are almost four times higher than in Vienna.

# Small regions (TL3)

Figure 2. Contribution to estimated GHG emissions

# Figure 3. Estimated GHG emissions per capita

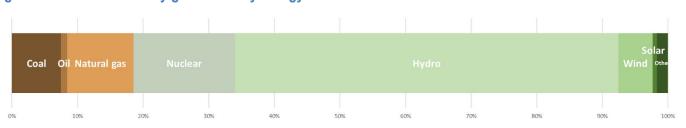

Across the OECD, metropolitan regions emit most greenhouse gases but per capita emissions are highest in remote regions. In Austria, a similar pattern can be observed. Emissions per capita in Austrian remote rural regions are higher than in large metropolitan regions.

# **ENERGY**

# Austrian electricity mix

Figure 4. National electricity generation by energy source in 2019

# Share of coal-fired electricity generation

2019 OECD average: 23%

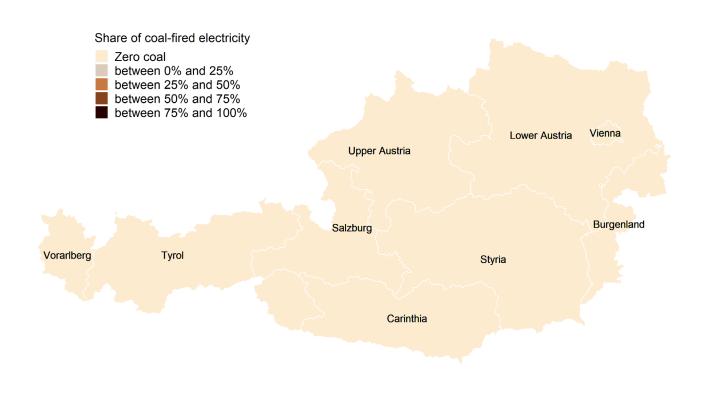

2019 Austrian average: 5%

2030 well below 2°C benchmark for the EU: <2%

2030 1.5°C benchmark for OECD countries: 0%

Figure 5. Regional coal-fired electricity generation estimates

Per cent of total electricity generation, large regions (TL2), 2017

According to the IEA, Austria uses coal for 5% of electricity generation. The regional estimates did not pick up on any coal-fired electricity generation capacity. Smaller scale facilities are sometimes not observed. No new capacity is planned or being build.

# Wind power

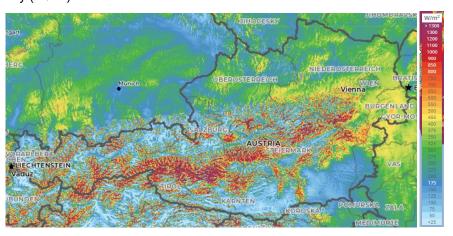

2019 OECD average: 8%

2019 Austrian average: 5%

2030 well below 2°C benchmark for the EU: >29%

# Figure 6. Wind power potential

Mean wind power density (W/m<sup>2</sup>)

Source: Map produced by The Global Wind Atlas

# Solar power

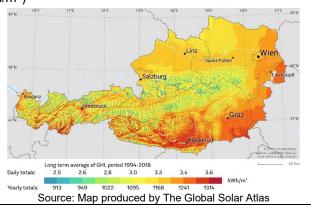

2019 OECD average: 3%

2019 Austrian average: 2%

2030 well below 2°C benchmark for the EU: >14%

# Figure 7. Solar power potential

Global horizontal irradiation (kWh/m²)

Although Austria already has a high share of zero emissions electricity generation, there is still scope for more solar and wind power. The national average shares of solar and wind are far below the 2030 benchmarks. Wind power density is highest in north-eastern regions, solar power potential is higher in the south.

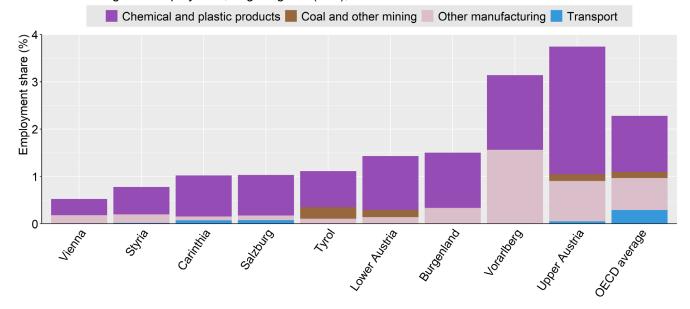

Benchmark notes: The well-below 2 degrees benchmarks show IEA Sustainable Development Scenario (SDS) numbers. The SDS models how the global energy system can evolve in alignment with the Paris Agreement's objective to keep the global average temperature increase well below 2°C above pre-industrial levels. According to the Powering Past Coal Alliance (PPCA), a phase-out of unabated coal by 2030 for OECD countries is cost-effective to limit global warming to 1.5°C.

Figure notes: Figure 4 shows data from the IEA (2020). Figure 5 shows OECD calculations based on the Power Plants Database from the WRI. The database captures electricity generation from the power plants connected to the national power grid. As a result, small electricity generation facilities disconnected from the national power grid might not be captured. See <a href="here">here</a> for more details. Figures 6 and 7 show the power potential of solar and wind. Mean wind power density (WPD) is a measure of wind power available, expressed in Watt per square meter (W/m²). Global horizontal irradiation (GHI) is the sum of direct and diffuse irradiation received by a horizontal surface, measured in kilowatt hours per square metre (kWh/m²).

# SECTORAL EMPLOYMENT RISKS

Figure 8. Employment in selected sectors which may be subject to employment loss by 2040 if emissions are reduced in line with the Paris climate agreement

Per cent of total regional employment, large regions (TL2), 2017

There will be both employment gains and losses due to the transition to net zero greenhouse gas emissions. They may not be distributed in the same way across regions. Employment in sectors that may be subject to some job loss by 2040 as a result of policies to reduce emissions in line with the climate objectives in the Paris Agreement amounts to less than 4% in all Austrian regions. Most Austrian regions have less employment in these sectors than the OECD average. Upper Austria and Vorarlberg have a larger share, largely driven by chemicals. The selection of sectors is broad and based on employment effects simulated across OECD countries (See Box 3.9 of the 2021 OECD Regional Outlook). It does not take specific local characteristics into account.

Figure notes: Figure 8 is based on data from OECD Statistics. Sectors are selected based on macroeconomic simulations of a scenario limiting global warming to well below 2 degrees. See Box 3.9 in the 2021 OECD Regional Outlook for more details.

# **TRANSPORT**

#### Electrification of passenger cars

2019 Austrian average share of full-electric new passenger car sales: 3%

Benchmarks for new zeroemission passenger car sales:

IEA well-below 2°C benchmark: 100% by 2040.

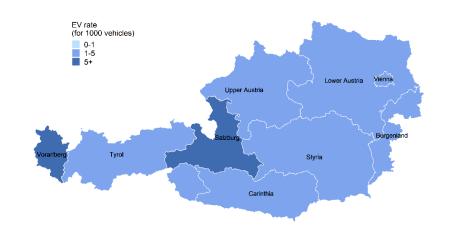

Aligned with net zero emissions by 2050: 100% by 2035 at the latest. 2030 cost-effective. Austrian target sales of zero emission new passenger cars:

No phase out date of internal

combustion cars yet

Figure 9. Full-electric road motor vehicles stock

Per 1000 vehicles, large regions (TL2), 2018

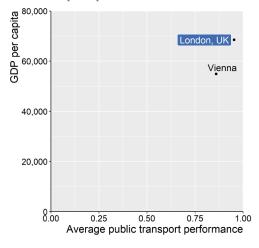

Most Austrian regions have less than five full-electric vehicles per 1000 road motor vehicles. Vorarlberg has, with about 8 full-electric vehicles per 1000 vehicles, the largest share of full-electric vehicles in its road motor vehicles stock. Salzburg follows with around five full-electric vehicles per 1000 road motor vehicles.

Countries with a net zero target by 2050 will need to phase out sales of new conventional cars by 2035 at the latest (considering cars have an average useful life of 15 years). A phase-out by 2030 is more cost-effective.

#### Modal shift

Public transport performance data is not yet available for many Austrian metropolitan areas. Vienna has a relatively good public transport performance. For comparison, London (UK) has among the highest public transport performance scores. Inhabitants of the metropolitan area of London can on average reach 95% of the population living within 8 km in 30 minutes by public transport.

Figure 10. Public transport performance in 2018

Benchmark notes: In the IEA's Sustainable Development Scenario, OECD countries (such as the European Union, Japan and the United States) as well as China fully phase out conventional car sales by 2040. This scenario is aligned with the Paris Agreement's objective to keep the global average temperature increase well below 2°C above pre-industrial levels. The UK Committee on Climate Change finds that all new cars and vans should be electric (or use a low carbon alternative such as hydrogen) by 2035 at the latest to reach net zero GHG emission targets by 2050. A more cost-effective date from the point of view of users is 2030.

Figure notes: Figure 9 is based on data from Statistics Canada. Figure 10 is based on data from ITF and OECD Statistics. See Box 3.10 in the 2021 OECD Regional Outlook for more details. GDP per capita is expressed in USD per head, PPP, constant prices from 2015.

# **AIR POLLUTION**

#### Large regions (TL2)

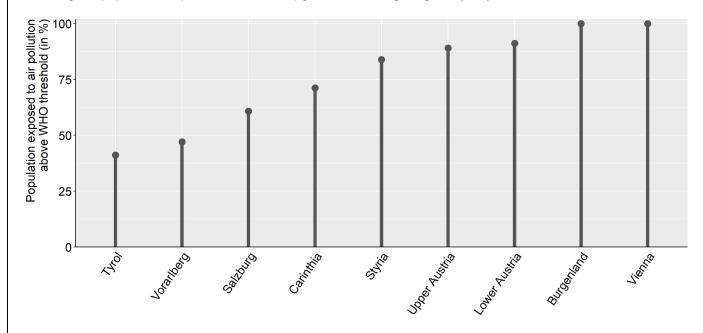

2019 OECD share of population exposed above the WHO-recommended threshold: 62%

2019 Austrian share of population exposed above the WHO-recommended threshold: 82%

WHO-recommended air quality threshold: PM2.5 annual mean concentration < 10 µg/m<sup>3</sup>

Figure 11. Share of population exposed to levels of air pollution above the WHO-recommended threshold

Percentage of population exposed to above 10 µg/m³ PM2.5, large regions (TL2), 2019

Policies towards net-zero greenhouse gas emissions can bring many benefits beyond halting climate change. They include reduced air and noise pollution, reduced traffic congestion, healthier diets, enhanced health due to increased active mobility, health benefits through thermal insulation, and improved water, soil and biodiversity protection. Some are hard to quantify.

In most regions over 50% of the population is exposed to small particulate matter air pollution above the WHO threshold. Small particulate matter (PM2.5) is the biggest cause of human mortality induced by air pollution. Major disease effects include stroke, cardiovascular and respiratory disease. Air pollution amplifies respiratory infectious disease such as Covid-19. It affects children the most. It reduces their educational outcomes as well as worker productivity.

Figure notes: Figure 11 is based on data from OECD Statistics.
