# EMISSIONS 2018 Spanish average: Spanish target: 7.2 tCO<sub>2</sub>e/capita net zero GHG emissions by 2050

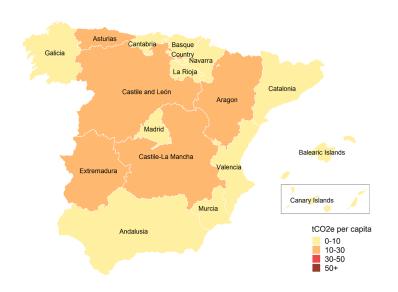

# Large regions (TL2)

2018 OECD average:

11.5 tCO₂e/capita

Figure 1. Estimated regional greenhouse gas emissions per capita

Tons CO<sub>2</sub> equivalent (tCO<sub>2</sub>e), large regions (TL2), 2018

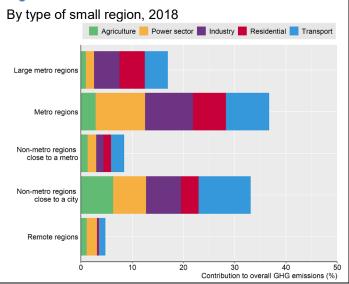

Greenhouse gas (GHG) emissions per capita generated in the majority of Spanish large regions are below 10 tCO<sub>2</sub>e per capita. Only Ceuta, Asturias, Aragon, Castile and Léon, and Castile-La Mancha have higher emissions per capita than the OECD average of 11.5.

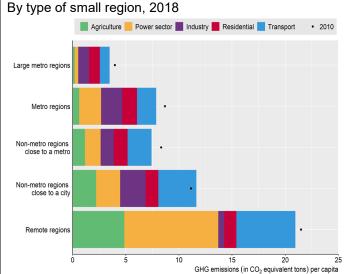

Estimated emissions per capita in Asturias are seven times higher than in Madrid.

# Small regions (TL3)

Figure 2. Contribution to estimated GHG emissions

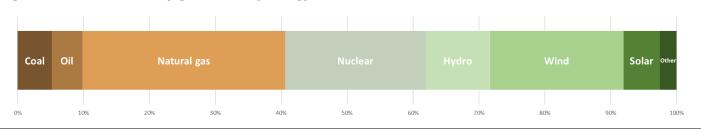

Across the OECD, metropolitan regions emit more greenhouse gases than rural regions. In Spain, a similar pattern can be observed. Emissions per capita in Spanish remote rural regions are much higher than in metropolitan regions. The difference is more pronounced than for the average OECD country.

# **ENERGY**

# Spanish electricity mix

Figure 4. National electricity generation by energy source in 2019

# Share of coal-fired electricity generation

2019 OECD average: 23%

2019 Spanish average: 5%

2030 well below 2°C benchmark for the EU: <2% 2030 1.5°C benchmark for OECD countries: 0%

Figure 5. Regional coal-fired electricity generation estimates

Per cent of total electricity generation, large regions (TL2), 2017

Most regions do not use coal in electricity generation. No new capacity is planned or being build.

# Wind power

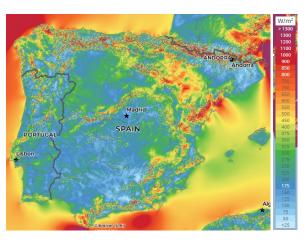

2019 OECD average: 8%

2019 Spanish average: 20%

2030 well below 2°C benchmark for the EU: >29%

# Figure 6. Wind power potential

Mean wind power density (W/m<sup>2</sup>)

Source: Map produced by The Global Wind Atlas

# Solar power

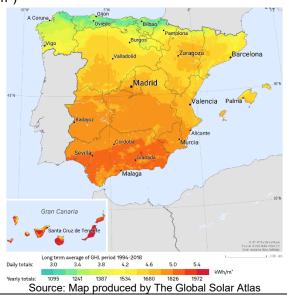

2019 OECD average: 3%

2019 Spanish average: 5%

2030 well below 2°C benchmark for the EU: >14%

# Figure 7. Solar power potential

Global horizontal irradiation (kWh/m2)

The national average shares, particularly for solar power, are far below the 2030 benchmarks. Wind power density is highest offshore and the north, solar power potential is higher in southern regions.

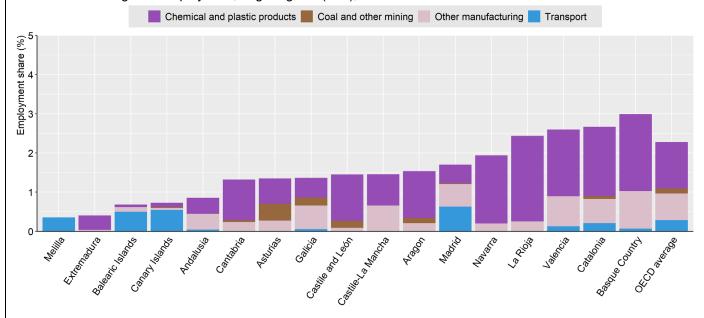

Benchmark notes: The well-below 2 degrees benchmarks show IEA Sustainable Development Scenario (SDS) numbers. The SDS models how the global energy system can evolve in alignment with the Paris Agreement's objective to keep the global average temperature increase well below 2°C above pre-industrial levels. According to the Powering Past Coal Alliance (PPCA), a phase-out of unabated coal by 2030 for OECD countries is cost-effective to limit global warming to 1.5°C.

Figure notes: Figure 4 shows data from the IEA (2020). Figure 5 shows OECD calculations based on the Power Plants Database from the WRI. The database captures electricity generation from the power plants connected to the national power grid. As a result, small electricity generation facilities disconnected from the national power grid might not be captured. See <a href="here">here</a> for more details. Figures 6 and 7 show the power potential of solar and wind. Mean wind power density (WPD) is a measure of wind power available, expressed in Watt per square meter (W/m²). Global horizontal irradiation (GHI) is the sum of direct and diffuse irradiation received by a horizontal surface, measured in kilowatt hours per square metre (kWh/m²).

# SECTORAL EMPLOYMENT RISKS

Figure 8. Employment in selected sectors which may be subject to employment loss by 2040 if emissions are reduced in line with the Paris climate agreement

Per cent of total regional employment, large regions (TL2), 2017

There will be both employment gains and losses due to the transition to net zero greenhouse gas emissions. They may not be distributed in the same way across regions. Employment in sectors that may be subject to some job loss by 2040 as a result of policies to reduce emissions in line with the climate objectives in the Paris Agreement amounts to less than 3.5% in all Spanish regions. Most Spanish regions have less employment in these sectors than the OECD average. Basque Country, Catalonia, Valencia and La Rioja have a relatively large share, largely driven by chemicals. The selection of sectors is broad and based on employment effects simulated across OECD countries (See Box 3.9 of the 2021 OECD Regional Outlook). It does not take specific local characteristics into account.

Figure notes: Figure 8 is based on data from OECD Statistics. Sectors are selected based on macroeconomic simulations of a scenario limiting global warming to well below 2 degrees. See Box 3.9 in the 2021 OECD Regional Outlook for more details.

# **TRANSPORT**

## Electrification of passenger cars

2019 Spanish average share of full-electric new passenger cars: 1%

Benchmarks for new zeroemission passenger car sales:

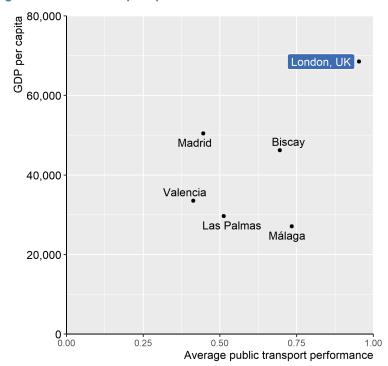

IEA well-below 2°C benchmark: 100% by 2040.

Aligned with net zero emissions by 2050: 100% by 2035 at the latest, 2030 cost-effective. Spanish target sales of zero emission new passenger cars: 100% by 2040

#### **Modal shift**

Public transport performance data is not yet available for all Spanish metropolitan areas. Despite having the lowest GDP per capita Málaga has the best public transport performance. For comparison, London (UK) has among the highest public transport performance scores. Inhabitants of the metropolitan area of London can on average reach 95% of the population living within 8 km in 30 minutes by public transport.

Benchmark notes: In the IEA's Sustainable Development Scenario, OECD countries (such as the European Union, Japan and the United States) as well as China fully phase out conventional car sales by 2040. This scenario is aligned with the Paris Agreement's objective to keep the global average temperature increase well below 2°C above preindustrial levels. The UK Committee on Climate Change finds that all new cars and vans should be electric (or use a low carbon alternative such as hydrogen) by 2035 at the latest to reach net zero GHG emission targets by 2050. A more cost-effective date from the point of view of users is 2030.

Figure notes: Figure 9 is based on data from ITF and OECD Statistics. See Box 3.10 in the 2021 OECD Regional Outlook for more details. GDP per capita is expressed in USD per head, PPP, constant prices from 2015.

# **AIR POLLUTION**

## Large regions (TL2)

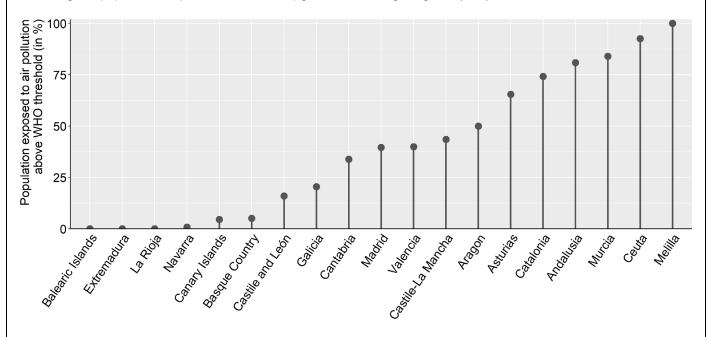

2019 OECD share of population exposed above the WHO-recommended threshold: 62%

2019 Spanish share of population exposed above the WHO-recommended threshold: 47%

WHO-recommended air quality threshold: PM2.5 annual mean concentration < 10 µg/m<sup>3</sup>

Figure 10. Share of population exposed to levels of air pollution above the WHO-recommended threshold

Percentage of population exposed to above 10 µg/m³ PM2.5, large regions (TL2), 2019

Policies towards net-zero greenhouse gas emissions can bring many benefits beyond halting climate change. They include reduced air and noise pollution, reduced traffic congestion, healthier diets, enhanced health due to increased active mobility, health benefits through thermal insulation, and improved water, soil and biodiversity protection. Some are hard to quantify.

In most regions at least 25% of the population is exposed to small particulate matter air pollution above the WHO threshold. Small particulate matter (PM2.5) is the biggest cause of human mortality induced by air pollution. Major disease effects include stroke, cardiovascular and respiratory disease. Air pollution amplifies respiratory infectious disease such as Covid-19. It affects children the most. It reduces their educational outcomes as well as worker productivity.

Figure notes: Figure 10 is based on data from OECD Statistics.
