Foreword

This report provides a comprehensive tax policy assessment of the taxes paid by individuals in Slovenia and makes recommendations for tax reform. The report is divided into six chapters, starting with a general chapter which sets the scene for tax reform in Slovenia (Chapter 1) and a chapter which focuses on the labour market, social policy and tax policy related challenges (Chapter 2). The following chapters assess the financing of the social security system (Chapter 3) and identify strategies to strengthen the design of the personal income tax (Chapter 4), indirect taxes (Chapter 5), and the taxation of capital income at the individual level (Chapter 6). The main findings of the report are summarised upfront; more detailed recommendations are included at the end of chapters 3 to 6.

This report will be included in the OECD Tax Policy Reviews. The Reviews are intended to provide independent, comprehensive and comparative assessments of OECD member and non-member countries' tax systems as well as concrete recommendations for tax policy reform. By identifying tailored tax policy reform options, the objective of the Reviews is to enhance the design of existing tax policies and to support the adoption of new reforms.

This report was written by Bert Brys, Céline Colin and Seán Kennedy and the project was led by Bert Brys. The analysis is primarily based on desk research, OECD statistics and tax modelling tools including an analysis based on a micro-dataset of income data from taxpayers provided by the Ministry of Finance of Slovenia. The analysis of the micro-data was carried out by Seán Kennedy. The VAT micro-simulation analysis included in chapter 5 was carried out by Alastair Thomas. The analysis was also based on a fact-finding mission which took place in Ljubljana in February 2018. During this mission, the OECD team spoke with a wide range of stakeholders and their valuable input is kindly acknowledged. The authors of the report would like to thank also the Ministry of Finance of Slovenia for their assistance in organising the mission and for follow-up support in the drafting stage of the review.

The authors wish to thank Mateja Vraničar Erman, Minister of Finance of Slovenia, Tilen Božič, State Secretary and Irena Popovič, Director General of the Directorate for the System of Tax, Customs and Other Public Finance Revenues from the Ministry of Finance of Slovenia, as well as their teams who have provided valuable input and guidance. Thank you in particular to Meta Šinkovec from the Ministry of Finance and Avgustin Staric from the Financial Administration. Thank you also to Irena Sodin, Ambassador, Permanent Representative to the OECD. The authors wish to thank Sarah Perret, Dominique Paturot, Pierce O'Reilly, Alastair Thomas, David Bradbury and Pascal Saint-Amans from the OECD Centre for Tax Policy and Administration for their helpful suggestions and input. The authors are also thankful to Jens Hoj from the Slovenia desk in the Economics Department of the OECD and to Francesca Colombo, Head of the Health Division in the OECD Directorate of Employment, Labour and Social Affairs. Thank you also to Carrie Tyler for her guidance on communications.

| Foreword | 3 |
| Executive summary | 11 |
| Main findings | 15 |
| Setting the scene for comprehensive revenue-neutral tax reform..... | 15 |
| Key elements of a comprehensive tax reform in Slovenia..... | 17 |
| A revenue neutral reform package | 21 |
| Slovenia needs a labour market reform that goes beyond taxation..... | 24 |
| Chapter 1. Setting the scene for tax reform in Slovenia | 25 |
| 1.1. After a double dip crisis Slovenia’s economy is recovering but the country continues to face..... major economic challenges..... | 25 |
| 1.2. Disposable income inequality is low | 27 |
| 1.3. The tax-to-GDP ratio is relatively high and the tax mix is somewhat unbalanced..... | 29 |
| 1.4. Government expenditures have declined but ageing-related costs might reverse this trend | 31 |
| 1.5. Local governments rely on revenues from the PIT and property taxes | 34 |
| 1.6. Slovenia faces a window of opportunity for a comprehensive tax reform..... | 36 |
| Chapter 2. Labour market, social policy and tax policy related challenges in Slovenia | 41 |
| 2.1. The labour tax burden is high but the personal income tax base is narrow | 41 |
| 2.2. Too few young and older people are active in the labour market..... | 47 |
| 2.3. Low levels of skills have a negative impact on productivity | 51 |
| 2.4. Wages are relatively low and the income distribution is narrow | 52 |
| 2.5. The welfare system faces financing challenges | 60 |
| Chapter 3. Tackling the challenges to finance the social security system | 63 |
| 3.1. High social security contributions distort the functioning of the labour market..... | 63 |
| 3.2. Stimulate labour market activity through a cut in the employee SSC rate | 67 |
| 3.3. Find alternative way of financing the welfare system | 73 |
| 3.4. Reform the SSCs paid by self-employed | 78 |
| 3.5. Align the SSC treatment across different type of employment contracts | 81 |
| 3.6. Increase the financial resources for health care | 83 |
| 3.7. Main recommendations..... | 87 |
| Chapter 4. Strengthening the design of the Personal Income Tax | 89 |
| 4.1. Redesign the PIT rate schedule..... | 89 |
| 4.2. Unify and broaden the PIT base..... | 103 |
| 4.3. Reduce tax disparities between different legal forms | 114 |
| 4.4. Main recommendations..... | 118 |
| Chapter 5. Improving the design of indirect taxes | 121 |
| 5.1. Slovenia has a standard VAT rate above the OECD average levied on a narrow base | 121 |

| | |
|---|------------|
| 5.2. Scope exists to improve distributional outcomes of the VAT system | 123 |
| 5.3. Excise duties can play a bigger role in financing the health system | 126 |
| 5.4. Main recommendations..... | 129 |
| Chapter 6. Strengthening the taxation of capital income at the individual level..... | 131 |
| 6.1. Slovenia faces modest opportunities to rebalance the tax mix towards higher taxes on capital income at the individual level..... | 131 |
| 6.2. Strengthen the taxation of household savings..... | 132 |
| 6.3. Raise more revenues from taxes on immovable property | 142 |
| 6.4. Main recommendations..... | 146 |
| References | 147 |
| Annex..... | 151 |
| Microdata..... | 151 |
| Comparison with survey data..... | 151 |
| Tax coverage of microdata..... | 152 |
| Total income by income category..... | 152 |
| Taxpayer classifications..... | 153 |
| Methodology of the costing of the main recommendations..... | 154 |

Executive summary

Slovenia needs a comprehensive tax reform that rebalances the tax mix away from employee social security contributions towards the personal income tax. The reform has to be (at least) revenue neutral. In the report “Reshaping the Personal Income Tax in Slovenia”, the OECD presents a tax reform package that seeks to prepare Slovenia for the ageing of its population.

1. **Slovenia needs a comprehensive tax reform that rebalances the tax mix away from employee social security contributions (SSCs) towards the personal income tax (PIT) and less distortive taxes such as the VAT and recurrent taxes on immovable property.** The tax reform will have to prepare Slovenia for the ageing of its population. The reform should incentivise older workers to stay in the labour market longer and younger workers to enter the labour market sooner and should reduce unemployment, in particular of the low-skilled. In order to put the funding of the welfare system on a solid footing without reducing entitlements to social benefits, the reform will need to shift the funding of the pension and health system partly from SSCs towards general taxation. The tax reform will need to go hand in hand with a broader set of reforms, including the reform of the pension and health care systems.
2. **A comprehensive tax reform will have to be (at least) budget neutral and be aligned with the country’s fiscal rule.** Over the past two decades, Slovenia has undertaken a number of extensive reforms. Some of these reforms were not fully funded, resulting in significant budget deficits that built up to as much as one quarter of the current public debt of Slovenia. More recently, the government has managed to significantly narrow the budget deficit. The level of public debt has been falling since 2016, while the country’s highly redistributive tax and benefit system has been maintained. A comprehensive tax reform should therefore ensure that public debt can be reduced further.
3. **The population in Slovenia is ageing rapidly with over 30% of the population projected to be older than 65 by 2050, which will be one of the highest proportions in the OECD.** The increase in age-related expenditure, especially on health and public pensions will put pressure on the budget and require accompanying fiscal measures. In addition, population ageing will reduce PIT and SSC revenues, thereby further increasing the challenges associated with financing the costs of an ageing population.
4. **Older workers leave the labour market in Slovenia too soon.** While Slovenia is the top performer in the OECD with respect to the employment rate of workers in the prime age category of 25-54, for both men and women, it is one of the weakest performers with respect to the labour market participation of its workers who are older than 54. The 2013 pension reform increased the legal retirement age to 65 for both men and women, which is having positive effects on the number of workers in employment aged 55+. Nevertheless, tax return data for the year 2016 reveals that there is still a significant gap between the official retirement age and the actual age of retirement. Such a low rate of participation of older workers in the labour market is unsustainable, particularly in the

context of Slovenia's ageing population. Further efforts to continue increasing the effective retirement age are needed.

5. **A well-designed PIT is the cornerstone of a tax system that favours inclusive economic growth.** While the PIT raises 25% of total tax revenues on average in the OECD, it raises only 14% in Slovenia. In contrast, SSCs raise 26% of total tax revenues on average in the OECD, while they raise almost 40% of tax revenues in Slovenia.
6. **By broadening the PIT base, Slovenia has an opportunity to rebalance the tax mix away from employee SSCs towards the PIT.** The combination of high employee and employer SSCs and progressive PIT rates results in very high and distortive tax burdens on labour income. It reduces incentives for employers to hire workers and for individuals to participate in the labour market and to increase work efforts. The narrow PIT base presents a challenge for reshaping the role of the PIT in Slovenia, and the PIT base should therefore be broadened.
7. **Opportunities also exist to rebalance the tax mix towards taxes on capital income at the individual level.** The recent move towards the automatic exchange of financial account information (AEOI) between tax administrations creates an opportunity for countries to reassess the way they tax personal capital income under the PIT system.
8. In addition to broadening the PIT base, there is some scope to finance a cut in SSCs by **broadening the VAT base** and by **strengthening the role of the recurrent tax on immovable property** in the financing mix of municipalities away from revenues from the PIT.

Main tax reform measures

9. **A stronger role for the PIT in Slovenia would allow a significant reduction in employee SSCs in the order of 5 percentage points.** Such a reform would encourage greater workforce participation among workers who are not currently active in the labour market, including low-income, low-skilled and older workers.
10. **A cut in employee SSCs would require re-designing the PIT rate schedule in order to balance the budget.** First, the top PIT bracket could be abolished. The current top PIT rate of 50% is too high, in particular in combination with the high employee SSCs. The combined employee SSC and top PIT rate in Slovenia is 61%, which is the highest of the OECD. Very few taxpayers pay the top PIT rate as it hits at very high income levels; abolishing the 50% top PIT rate bracket would, therefore, only have a small impact on PIT revenue.
11. **Second, the tax rates in the second, third and fourth tax bracket (respectively 27%, 34% and 39%) could be increased to help finance the cut in employee SSCs.** The increase in the PIT rates would depend on the size of the reduction in employee SSCs. The PIT rate in the bottom bracket (16%) could be kept unchanged in order to maximise the impact of the cut in employee SSCs on low-income workers. The PIT rates in the third and fourth bracket could be increased more than the rate in the second bracket. However, the PIT rate in the fourth bracket (i.e. the new top PIT rate) should not be higher than 45%.
12. **To compensate for the high tax burden on labour income, Slovenia has generous tax provisions that lower the tax burden in particular for families with children** as they benefit from both child tax allowances and child cash benefits. The design and interaction of these provisions is complex and could be reformed.

13. **Ample scope exists to broaden the PIT base.** The PIT base is narrow as a result of exemptions and special tax provisions. First, tax provisions in Slovenia take the form of tax allowances, which give a larger tax reduction to higher incomes. This is not aligned with best practice in the OECD, where tax credits are more widely used as tax credits provide the same benefit to all taxpayers irrespective of their income and marginal tax rates. Second, broadening the tax base can in particular be achieved by abolishing the tax exemption for the reimbursement of home-work travel expenses and meals during work and by taxing performance bonuses and annual bonuses as regular income under the PIT.
14. **The SSC base could be broadened by limiting the number of different contribution rates and bases, and aligning the treatment of different types of incomes.** A cut in employee SSCs would also imply that the SSCs that the self-employed have to pay, which are high by international comparison, would be reduced.
15. **High tax burdens on labour income and high tax compliance costs reduce the incentives for entrepreneurship.** In response, Slovenia has introduced an alternative “flat-rate” tax regime for self-employed entrepreneurs. However, the design of this regime induces entrepreneurs to conceal their income and discourages businesses from growing. The flat-rate regime is very generous in that it allows a deduction of “presumptive costs” equal to 80 per cent of income, which is significantly higher than the actual costs incurred by most businesses. This approach not only results in low PIT liability but also reduces the SSC base. The flat-rate regime needs to be reformed and, possibly, abolished.
16. **Self-employed who do not opt for the generous “flat-rate” regime have a tax-induced incentive to incorporate** in order to transform highly taxed labour income into low-taxed capital income. The tax burden on labour and capital income needs to be more closely aligned by lowering the tax burden on labour income and increasing the tax burden on capital income.
17. **The financing of the health system needs to be strengthened. In this regard, there are a wide range of measures available.** However, an in-depth evaluation of the efficiency of the health and welfare systems should be undertaken. Such an evaluation would be welcome along-side the introduction of measures that would allow the Health Insurance Institute of Slovenia (HIIS) to focus on its core activities and to put its financing on a more sustainable footing in light of the challenges linked to the ageing of society.

Main findings

Setting the scene for comprehensive revenue-neutral tax reform

18. **A well-designed personal income tax (PIT) is the cornerstone of a tax system that favours inclusive economic growth.** Slovenia needs a comprehensive tax reform that rebalances the tax mix away from employee social security contributions (SSCs) towards the PIT as well as the VAT and recurrent taxes on immovable property. The tax reform will have to prepare Slovenia for the ageing of its population. The reform should incentivise older workers to stay in the labour market longer and younger workers to enter the labour market sooner and should reduce unemployment, in particular among the low-skilled. In order to put the funding of the welfare system on a solid footing without reducing entitlements to social benefits, the reform will need to shift the funding of the pension and health system partly from SSCs towards general taxation. The tax reform will need to go hand in hand with a broader set of reforms, including the reform of the pension and health care systems.
19. **A comprehensive tax reform will have to be (at least) budget neutral and be aligned with the country's fiscal rule and budgetary obligations as a member state of the European Union.** The level of public debt has increased sharply: from 22% of GDP in 2008 to more than 82.6% of GDP in 2015. Over the past two decades, Slovenia has undertaken a number of extensive reforms. Some of these reforms were not fully funded, resulting in significant budget deficits that built up to as much as one quarter of the current public debt of Slovenia. More recently, the government has managed to narrow the budget deficit. The level of public debt has been falling since 2016, while the country's highly redistributive tax and benefit system has been maintained. Also, privatisation has reduced contingent liabilities somewhat, although state-ownership remains at an internationally high level. A comprehensive tax reform should therefore ensure that public debt can be reduced further.
20. **The population in Slovenia is ageing rapidly with over 30% of the population projected to be older than 65 by 2050, which will be one of the highest proportions of older people in the OECD.** The increase in age-related expenditure, especially on health and public pensions will put pressure on the budget and require accompanying fiscal measures. In addition to increasing pressures on public spending, which in itself will require reform, population ageing will reduce tax revenues. Currently, labour taxes (i.e. PIT and SSCs) account for a large share of Slovenia's tax revenues. A reduction in the share of people who are active in the labour market will significantly lower these tax revenues, thereby further increasing the challenges associated with financing the costs of an ageing population.
21. **Older workers leave the labour market in Slovenia too early.** While Slovenia is the top performer in the OECD with respect to the employment rate of workers in the prime age category of 25-54, for both men and women, it is one of the weakest performers with respect to the labour market participation of its workers who are older than 54. The 2013

pension reform increased the legal retirement age to 65 for both men and women, which is having positive effects on the number of workers in employment aged 55 and above. Nevertheless, analysis of tax return data for the tax year 2016 reveals that there is still a significant gap between the official and actual age of retirement. Such a low participation rate among older workers in the labour market is unsustainable, particularly in the context of Slovenia's ageing population. Further efforts to continue increasing the effective retirement age are needed.

22. **Slovenia faces other labour market challenges that need to be addressed**, including low youth labour market participation because of long study periods, high long-term unemployment, particularly amongst the low-skilled, and inequities in the tax treatment of different types of workers.
23. **PIT accounts for a comparatively small share of revenues in Slovenia**. While the PIT raises 25% of total tax revenues on average in the OECD, it raises only 14% in Slovenia. Low PIT revenues are not the result of low PIT rates or a lack of tax progressivity – in fact, the top PIT rate in Slovenia is comparatively high – but the consequence of a narrow PIT base due to many generous tax provisions and tax exemptions.
24. **SSCs raise a large share of revenues in Slovenia**. SSCs are usually levied at flat rates and revenues are typically earmarked for social welfare spending. On average in the OECD, SSCs account for 26% of total tax revenues, while they account for close to 40% of tax revenues in Slovenia. Nevertheless, a wide range of special SSC regimes narrow the SSC base. Despite the narrow SSC base, high SSC revenues reflect high SSC rates in Slovenia.
25. **By broadening the PIT base, Slovenia could rebalance its tax mix away from employee SSCs towards the PIT**. The combination of high employee and employer SSCs and progressive PIT rates results in very high and distortive tax burdens on labour income. It reduces incentives for employers to hire workers and for individuals to participate in the labour market and to increase work efforts. The narrow PIT base presents a challenge for reshaping the role of the PIT in Slovenia, and the PIT base should therefore be broadened.
26. **Opportunities also exist to rebalance the tax mix towards taxes on capital income at the individual level**. The recent move towards the automatic exchange of financial account information (AEOI) between tax administrations creates an opportunity for countries to reassess the way they tax personal capital income under the PIT system.
27. **In addition to broadening the PIT base, there is some scope to finance a cut in SSCs by broadening the VAT base**. A wide range of goods and services are taxed at a reduced VAT rate and provide the largest gain to richer households.
28. **There is also considerable scope to strengthen the role of the recurrent tax on immovable property in the financing mix of municipalities** away from revenues from the PIT towards a greater reliance on taxes on immovable property.
29. **In order to better prepare Slovenia for the future, tax reform will need to go hand in hand with a broader set of reforms**, including a pension reform and a reform of the health care system.
30. **This report provides an assessment of the taxes paid by individuals in Slovenia and outlines recommendations for tax reform**. It does not include an assessment of the taxes paid by corporations such as the corporate income tax (CIT) and the international tax rules in Slovenia. Such an assessment is beyond the scope of this analysis.

Key elements of a comprehensive tax reform in Slovenia

31. **A comprehensive tax reform will have to be pursued in the context of a tax-to-GDP level that is already above the OECD average** and relatively high in view of the income level in Slovenia, and a tax mix that is unbalanced and relies heavily on distortive taxes on labour. Slovenia has a sophisticated social welfare system which is successful in reducing income inequality. The system is financed largely through SSCs which are levied at very high rates, in particular for employees. However, there are discrepancies between the tax and SSC treatments of different types of workers, reducing transparency and increasing inequality.
32. **The combination of high employee and employer SSCs and progressive PIT rates results in very high tax burdens on labour income.** In general, it reduces incentives for employers to hire workers and for individuals to participate in the labour market and to increase work efforts, which is likely to be a particularly significant issue for workers with a weaker attachment to the labour market such as low-skilled workers and older workers.
33. **Slovenia imposes a minimum SSC base for workers under a certain income threshold**, which implies that employers have to pay higher effective SSC rates for low-income workers. This makes it expensive for employers to hire low-skilled and low-income workers and reduces the labour market opportunities for these types of workers.
34. **The combination of high taxes on labour income and the loss of out-of-work benefits for the unemployed who re-enter the labour market, results in high implicit tax rates on return to work for the unemployed** – also known as unemployment and inactivity traps. Young people also enter the labour market late because they extend their study period, which is linked to the generous tax treatment of income from student work. Recent reforms have reduced the tax privileges for students but their income continues to benefit from preferential tax treatment. Moreover, almost all workers leave the labour market when they reach the age of 59, which is reflected in the sharp income declines at and after this age. The 2013 pension reform is having positive effects on the labour market participation of older workers but further reform efforts are necessary in order to significantly raise the effective retirement age of workers in Slovenia.
35. **To compensate for the high tax burden on labour income, Slovenia has generous tax provisions that lower the tax burden in particular for families with children.** While tax base narrowing measures can strengthen the fairness of the tax system by providing support to some taxpayers, they result in higher tax rates on the other taxpayers. Families with children benefit from both child tax allowances and child cash benefits. The design and interaction of these provisions is complex and needs to be reformed. Secondary earners, usually women, face very high marginal tax rates, partly as a result of the decline in child benefits at higher income levels
36. **A stronger role for the PIT in Slovenia would allow reductions in employee SSCs, possibly by phasing in the reduction over time.** Such a reform would encourage greater workforce participation among workers who are not currently active in the labour market, including low-income, low-skilled and older workers. Lower employer SSCs would stimulate labour demand, which would expand the tax base.
37. **A cut in employee SSCs would require re-designing the PIT rate schedule in order to balance the budget.** First, the top PIT bracket could be abolished. The current top PIT rate of 50% is too high, in particular in combination with the high employee SSCs. The

top marginal “all-in” rate, which takes into account employee SSCs and the top PIT rate in Slovenia is 61.1% which is the highest all-in rate that is levied in the OECD. Such a high combined tax rate strongly discourages taxpayers from increasing work efforts and may encourage tax avoidance, such as business incorporation in particular as the top rates on labour and capital income are not aligned. Very few taxpayers pay the top PIT rate as it is levied on very high income levels. Simulations based on tax return data show that reducing the top PIT rate would come at a low tax revenue cost. Even if the top PIT rate was lowered to 45%, the marginal “all-in” rate would continue to be above the rates that can be found in countries such as Austria, Italy, and Germany.

38. **The tax rates in the second, third and fourth tax bracket (respectively 27%, 34% and 39%) could be increased to help finance the cut in employee SSCs.** The increase in the PIT rates needed to compensate for the cut in employee SSCs would depend on the size of the reduction in employee SSCs. The PIT rate in the bottom bracket (16%) could be left unchanged in order to maximise the impact of the cut in employee SSCs on low-income workers. The PIT rates in the third and fourth bracket could be increased more than the rate in the second bracket. However, the PIT rate in the fourth bracket (i.e. the new top PIT rate) should not be higher than 45%.
39. **People on lower incomes face a lower tax burden, mainly as a result of generous basic allowances.** However, low-income workers face disincentives to move up the income scale as, in addition to the general tax allowance, there is an additional basic allowance which is reduced at higher income levels and therefore increases marginal effective tax rates. One possible option could include replacing both tax allowances by a single tax credit which would not vary with income, but to compensate for the tax revenue cost by increasing the bottom PIT rate.
40. **There is ample scope to broaden the PIT base, which would limit the extent to which PIT rates would have to be increased.** The PIT base is relatively narrow as a result of exemptions and special tax provisions. First, tax provisions in Slovenia take the form of tax allowances, which give a larger tax reduction to people earning higher incomes. This is not aligned with best practice in the OECD, where tax credits are more widely used as tax credits provide the same benefit to all taxpayers irrespective of their income and marginal tax rates. Among the tax provisions that could be abolished to broaden the PIT base are the tax exemption for the reimbursement of home-work travel expenses and meals during work. Across the OECD, the expenses that workers incur to earn taxable personal income, including home-work travel costs, are typically included in the basic allowance and therefore exempt from PIT through the basic allowance. Exempting the reimbursement for those expenses from tax, as is the case in Slovenia, results in a double tax exemption. In addition, the performance bonuses and annual bonuses, which are currently tax exempt up to the average wage, could be taxed as regular income under the PIT.
41. **The SSC base could be broadened by limiting the number of different contribution rates and bases, and aligning the tax treatment of different types of incomes.** A cut in employee SSCs would also imply that the SSCs that the self-employed have to pay, which are high by international standards, would be reduced. Slovenia could further align the SSC treatment of employees and the self-employed. However, this would not only imply a convergence in SSCs, but also a convergence in benefit entitlements for the different types of workers. As part of such a reform, Slovenia could consider introducing a SSC ceiling for employees or abolishing the ceiling for the self-employed; the latter reform would require an accompanying increase in the maximum pension for the self-

employed in order to ensure that the link between contributions made and benefits received remains intact. Such a reform would also require that, instead of exempting 25% of the income from tax, the income earned by the self-employed would be split in a return for work and a return for the capital invested; both returns could then be taxed separately.

42. **Generous tax provisions have long-run costs for the taxpayers who benefit from them.** The remuneration which workers receive for home-work travel and meals during work are exempt from PIT and SSC, which narrows the base and, thereby, reduces their effective tax burden. However, as taxpayers do not pay SSCs on tax-exempt income, they also do not build up rights to future benefit entitlements (e.g. a pension). While a narrow base might bring advantages in the short run for some taxpayers, it definitely comes at a cost for them and society in the longer run.
43. **The financing of the welfare system, including the health system, needs to be strengthened and a wide range of measures are available.** An in-depth evaluation of the efficiency of the welfare system, and in particular of the health fund, would be welcome along-side the introduction of measures that would allow the Health Insurance Institute of Slovenia (HIIS) to focus on its core activities and to put its financing on a more sustainable footing in light of the challenges linked to the ageing of society.
44. **While the link between SSCs and benefits could be strengthened, the link at low income levels could be made less stringent in order to prevent labour market distortions.** Wages and pensions in Slovenia are relatively low by OECD standards, although not necessarily in comparison with some other East European countries. Tax return data shows that the wage structure is compressed particularly at the low end of the wage distribution, which implies that financing the welfare state mainly through SSCs, as is the case in Slovenia, is very challenging as it requires levying very high SSC rates in order to raise sufficient revenues. While strengthening the link between the SSCs that workers pay and the benefits that they will receive constitutes good tax policy in general, in the presence of low wages and a condensed wage distribution it might be challenging to implement. In order to ensure that low income workers will be entitled to a minimum pension that prevents them from falling into poverty when they retire, very high SSCs are levied, which might price these workers out of the labour market. In such a setting, a more balanced financing mix of the welfare state beyond SSCs would be optimal and would prevent a drop in pension and other benefits. Indeed, the minimum SSC base for workers under a certain income threshold, which is planned to increase further, will be too high leading to very large effective employer SSC rates; this threshold should be abolished for both employees and self-employed or, if that would not be feasible in the short run, lowered to the minimum wage.
45. **The flat-rate regime for self-employed workers needs reform.** High tax burdens on labour income and high tax compliance costs reduce the incentives for entrepreneurship. In response, Slovenia has introduced an alternative “flat-rate” tax regime for self-employed entrepreneurs. However, the design of this regime encourages entrepreneurs to conceal their income and discourages businesses from growing. The flat-rate regime is very generous in that it allows a deduction of “presumptive costs” equal to 80 per cent of income, which is significantly higher than the actual cost incurred by a significant number of businesses. This approach not only results in low PIT liability but also reduces the SSC base. A large share of the self-employed under the “flat-rate” regime therefore pay SSCs on the minimum SSC base. Abolishing the “flat-rate” regime and the minimum SSC base therefore needs to go hand in hand.

46. **The self-employed who do not opt for the generous “flat-rate” regime have a tax-induced incentive to incorporate** in order to turn highly taxed labour income into low-taxed capital income. The tax burden on labour and capital income needs to be more closely aligned by lowering the tax burden on labour income and increasing the tax burden on capital income.
47. **Strengthening the design of consumption taxes could help finance a cut in SSCs.** The standard VAT rate is high and the reduced VAT rate, which is relatively low, applies to a large number of goods and services. As the VAT rate in neighbouring countries is somewhat lower than in Slovenia, the standard VAT rate should be maintained at its current level. However, there is scope to address regressive distributional effects of the reduced VAT rate in Slovenia. Some of the products and services that are taxed at the reduced VAT rate benefit the rich more than the poor both in relative and absolute amounts. This is the case for cultural activities, hotels, restaurants, and air transport.
48. **The recent move towards the automatic exchange of financial account information between tax administrations creates opportunities for Slovenia to revisit the way it taxes personal capital income.** Tax rates on capital income at the individual level in Slovenia are not particularly high and effective tax rates on household savings vary widely across assets. Some assets, such as owner-occupied and rental immovable property and private pension savings are taxed particularly lightly. The capital income tax system also lacks progressivity, which is typical under dual income tax systems. Slovenia could consider increasing the progressivity of its capital income tax system.
49. **Finally, improving the design of the tax system will also require property tax reform and changes to the way municipalities are financed.** The introduction of the new real estate tax is much-awaited as it creates opportunities to rebalance the tax mix and to reform the financing mix of local governments. Municipalities currently underutilise the recurrent tax on immovable property as they receive a significant share of the revenues from the PIT from central government. For instance, the formula that assigns additional tax revenues to municipalities could be adjusted to take into account the extent to which the municipality faces the opportunity to collect revenues from recurrent taxes on immovable property. Calculations presented in this report indicate that central government could lower the PIT revenue sharing ratio from 54% to 36% once the recurrent tax on immovable property is put in place and then continue lowering the ratio gradually over time to a ratio between 30% and 18%.
50. **Table 1 presents the key tax reform recommendations.** More detailed recommendations are included at the end of each chapter in this report.

Table 1. Key tax reform recommendations

| | |
|--|--|
| Strengthen the design of the PIT | <p>Abolish the top PIT rate</p> <p>Increase the PIT rates in the second, third and fourth tax bracket</p> <p>Broaden the PIT base, including by abolishing the exemption for the reimbursement of home-work travel expenses and meals during work and taxing performance and annual bonuses as regular income</p> <p>Abolish or reduce the generosity of the flat-rate regime for self-employed workers</p> <p>Redesign the provisions that provide support for children</p> <p>Reduce tax disparities between different businesses legal forms</p> <p>Publish an annual tax expenditure report and improve transparency</p> |
| Strengthen the social security system | <p>Reduce employee SSCs</p> <p>Lower the minimum SSC income base</p> <p>Broaden the SSCs base</p> <p>Evaluate the link between SSCs paid and benefits received</p> <p>Increase and diversify the sources of financing dedicated to health care</p> |
| Improve the design of indirect taxes | <p>Maintain the 22% standard VAT rate</p> <p>Broaden the VAT base by reducing the use of lower VAT rates</p> |
| Improve the taxation of capital income at the individual level | <p>Raise more revenues from taxing capital income at the individual level</p> <p>Revise the tax treatment of immovable property</p> |
| Reform the financing of municipalities | Partly shift the financing mix of municipalities |

A revenue neutral reform package

51. **The main tax reform recommendations presented in this report have been costed through micro-simulation analysis using information on income data from individual taxpayers for the fiscal year 2016.** The tax revenue potential of the recurrent tax on immovable property have been calculated on the basis of OECD Revenue Statistics data. VAT base broadening measures are based on micro-simulation analysis of Household Budget Survey information.
52. **According to the simulation analysis, a 5.24 percentage points reduction in employee SSCs (from 22.1% to 16.86%) is associated with a reduction in tax revenues of EUR 519 million.** The reduction in employee SSCs of 5.24 percentage points reflects a general reduction in employee SSCs of 5 percentage points augmented by the reduction in employee SSCs if the rates for unemployment insurance (at 0.14 pp) and maternity leave (at 0.10 pp) are put to 0. A reduction in employee SSCs of 5 percentage points has been chosen as it reflects a significant cut, but other assumptions could have been made. There is a reduction in SSC revenues of approximately EUR 700 million through lower employee SSCs but EUR 180 million (about one-quarter) is recovered through the PIT. This is the result of a direct and indirect PIT recovery channel. A reduction in employee SSCs broadens the PIT base which increases PIT revenues directly and also indirectly as some taxpayers might be pushed into higher PIT rate brackets. The PIT recovery could exceed SSC losses in the top PIT brackets. The analysis assumes no behavioural changes.
53. **Abolishing the top PIT rate bracket comes at a small revenue cost of EUR 13 million; lowering the top PIT rate from 50% to 45% would cost EUR 6 million.** The analysis shows that a two percentage point increase in the PIT rate of the second, third and fourth bracket, for instance, is estimated to raise EUR 61 million of extra revenues when employee SSCs remain at 22.1% and EUR 71 million if employee SSCs were

reduced to 16.86%. The estimations show that a narrow base comes at a significant revenue cost. Broadening the tax base by, for instance, 10% would raise additional revenue of EUR 120 million, which would be close to the cost of a 1 percentage point reduction in employee SSCs. The analysis also indicates that broadening the PIT base will require smaller PIT rate increases in order to finance a significant employee SSC cut. Finally, the SSC loss associated with introducing a cap at 350% of the average wage for employees is EUR 61 million and EUR 45 million for employee and employer SSCs respectively.

54. **Significant tax revenues could be raised through VAT base broadening.** Abolishing the reduced VAT rate on hotel accommodation and restaurant food, for instance, would collect an extra EUR 68 million. Higher statutory tax rates on capital income at the individual level would increase tax revenues only modestly. These simulations, however, do not take into account the additional information that the tax administration might receive through the AEOI between tax administrations of capital income earned by tax residents in Slovenia on assets held offshore but which have not yet been declared to the tax administration in Slovenia. However, an important amount of additional tax revenue could be raised by using the potential of the recurrent tax on immovable property. If Slovenia would raise revenues from the recurrent tax on immovable property equal to an amount which other OECD countries collect on average, it would collect an extra EUR 280 million. Increasing the revenues from recurrent taxes on immovable property to the level of the best performers in the OECD would allow Slovenia to raise EUR 670 million of additional tax revenues, which would correspond to a reduction in employee SSCs by 6.8 percentage points.

Table 2. Costing of main recommendations

| Main objective | Recommendation | Scenario | Change in revenues (EUR millions) | |
|--|--|---|--|------------------|
| Strengthen the design of the PIT | Abolish the top PIT rate | Abolish 50% top PIT rate and bracket | -13 | |
| | | Lowering top PIT rate to 45% (but maintain bracket) | -6 | |
| | Increase the PIT rates in the second, third and fourth tax bracket (note: estimates based on 2018 PIT schedule applied retrospectively to 2016 tax data; estimates presented are cumulative). | PIT rate increase for an employee SSC rate at 22.1% | Second bracket PIT rate: + 1, 2, 3, 4pp | 22, 45, 67, 90 |
| | | | Third bracket PIT rate: + 1, 2, 3, 4pp | 7, 14, 21, 28 |
| | | | Fourth bracket PIT rate: + 1, 2, 3, 4, 5, 6pp | 1, 2, 4, 5, 6, 7 |
| | | PIT rate increases for an employee SSC rate cut to 16.86% | Second bracket PIT rate: + 1, 2, 3, 4pp | 26, 51, 77, 103 |
| | | | Third bracket PIT rate: + 1, 2, 3, 4pp | 8, 17, 25, 34 |
| | | | Fourth bracket PIT rate: + 1, 2, 3, 4, 5, 6 pp | 1, 3, 4, 6, 7, 9 |
| | Broaden the PIT base | Reduce tax allowances | By 5% | 58 |
| | | | By 10% | 120 |
| By 15% | | | 184 | |
| By 20% | | | 251 | |
| By 25% | | | 319 | |
| Reform the social security system | Reduce employee SSC rates | Employee SSCs | From 22.1% to 16.86% | -519 |
| | Align the SSCs for regular employees and the self-employed | Apply SSC ceiling to employees at 350% of average wage | Employee SSC only | -61 |
| | | | Employer SSC only | -45 |
| | | Both | -106 | |
| Broaden the VAT base by reducing the use of lower VAT rates | Tax goods and services at the standard rate instead of a reduced VAT rate | All goods (including food) and services | 689 | |
| | | Books, newspapers, periodicals, cinema, theatre, concerts | 27 | |
| | | Hotel accommodation and restaurant food | 68 | |
| | | Passenger transport (excluding international air transport) | 17 | |
| Improve the taxation of capital income at the individual level | Raise more revenues from taxing capital income at the individual level | Increase in statutory tax rate on capital income | 5 pp | 18 |
| | | | 10 pp | 37 |
| | | | 15 pp | 55 |
| | Revise the tax treatment of immovable property | Increased use of recurrent taxes on immovable property to | Average across OECD countries (1.1% of GDP)* | 280 |
| | | | Good OECD performer (2% of GDP)* | 670 |
| | | | Best OECD performer (2.5% of GDP)* | 890 |

Note: Estimates are purely informative and provide an indication of the impact of each specific tax reform on total tax revenues holding all other tax characteristics unchanged (i.e. ceteris paribus). As a result, the different estimates cannot be simply added as the revenue impact of certain measures will depend on, and interact with, the impact of other measures. For instance, a reduction in employee SSCs and a corresponding PIT rate increase will interact with the revenue implications of PIT base broadening measures. Hence, the simultaneous introduction of various measures included in the table may have a different tax revenue impact than would be obtained by adding the presented revenue estimates of each measure in isolation. In addition the tax reform measures may lead to a reduction in the funding of different public funds (government budget, health fund, pension fund, local budgets); this will need to be taken into consideration when drafting the changes in a tax law. Furthermore, the reduction in employee SSC rates is presented as a net effect as it combines the reduction in SSC revenues with the increase in PIT revenues as a result of the base broadening effect of a reduction in employee SSCs (for more information: see chapter 4). * Calculations are based on the GDP figure from the Statistical Office of Slovenia (EUR 43,278 billion in 2017, current prices). Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata. The effects in Table 2 are calculated using 2016 data and take into account tax allowances and PIT rate schedule valid in 2016. Some tax parameters have changed since then. However, the increases in the PIT rates have been based on the 2018 PIT rate schedule which has been applied retrospectively to the 2016 tax data.

Slovenia needs a labour market reform that goes beyond taxation

55. **Tackling the challenge of low labour participation of young and in particular older workers and population ageing in Slovenia requires reforms that go beyond tax policy.** The retirement age has been increasing since the 2013 pension reform. Nevertheless, the gap between the legal and the actual retirement ages remains large as a result of pre-retirement schedules, the use of sickness leave as a bridge between work and retirement, etc. The abuse of these mechanisms should be prevented in order to increase the effective retirement age in Slovenia. In addition to measures that discourage early retirement, measures that make working longer financially more attractive could be implemented. Slovenia may also further develop systems that allow for a smooth transition between work and retirement such as, for instance, part-time work and part-time retirement schemes. The government should also consider increasing the legal retirement age from 65 to 67, as recommended in the OECD Economics Surveys: Slovenia 2017 (OECD, 2017_[14]). Such a measure could form part of a longer term proposal to lift the retirement age on a prospective basis.
56. **Wages in Slovenia increase automatically with the worker's age irrespective of the worker's labour market productivity,** which has negative implications for the work opportunities, particularly for older low-skilled workers, especially when considered in the context of high SSCs. Ideally, such an automatic increase in wages with age is replaced with an alternative system of remuneration.

Chapter 1. Setting the scene for tax reform in Slovenia

Slovenia enters the fifth year of economic recovery after the double dip crisis in 2008 and 2013. The government has managed to close the budget deficit and place public debt in a declining path. Slovenia continues to face major challenges which need to be addressed: public debt is high, the population is ageing, labour market participation rates are low for old and young workers, long-term unemployment is high, and labour productivity is relatively low. Without significant reforms, government will have to raise more tax revenues to face rising costs associated with an ageing population, maintain the generous transfers system that successfully reduces inequalities and poverty, and finance the multiple structural reforms needed. The ageing of the population will not only increase public spending but, in the absence of reform, will also put tax revenues under pressure. Tax and spending reforms will have to happen in the context of a tax level which is above the OECD average and a tax mix which is somewhat unbalanced and relies heavily on distortive taxes on labour. Improving the design of the tax system will also need to reform the financing of local municipalities.

1.1. After a double dip crisis Slovenia's economy is recovering but the country continues to face major economic challenges

57. **The international financial crisis (2008-09) followed by the Slovenian banking crisis (2013) weakened the economy but growth has now recovered.** In 2018 Slovenia enters the fifth consecutive year of steady economic recovery. The growth rate was 3.1% in 2016 and 5% in 2017 (Eurostat) which contrasts with the negative growth in 2012 (-2.7%) and 2013 (-1.1%). Initially, the recovery was led by exports, but it is increasingly being supported by stronger private domestic demand underpinned by real income growth, stronger employment and rising consumer confidence (OECD, 2017^[1]).
58. **The budget deficit and the debt-to-GDP ratio have decreased since 2014.** In 2017 the general government budget registered a small surplus (Ministry of Finance, 2018^[2]), and Slovenia exited the European Commission's excessive deficit procedure (Figure 1.1). A budget surplus is expected also in 2018. The debt-to-GDP has quadrupled from 22% in 2008 to more than 82% of GDP in 2015, as a consequence of the 2006-07 tax reform, which was not revenue neutral, and the banking sector bail-out in 2013 (Figure 1.2). More recently, the government has managed to narrow the budget deficit and the level of public debt has been falling since 2016. Also privatisation has reduced contingent liabilities somewhat, although state-ownership remains at an internationally high level. The debt-to-GDP ratio had decreased by 9 percentage points from 2015 to 2017 (to 73.6% of GDP). According to the IMF projections public debt is expected to reach 77% of GDP in 2018 (IMF, 2017^[3]). The government's objectives for 2020 are to eliminate the structural budget deficit and to have a debt-to-GDP ratio close to 60%.

Figure 1.1. The budget deficit is closing

Figure 1.2. Public debt has stabilised but remains high

Note: * are estimates.

Source: IMF, World Economic Outlook Database, October 2017; Ministry of Finance of Slovenia.

59. **The ageing population will put more pressure on public spending.** Since independence the share of elderly people has increased and could represent a third of the population by 2060¹ (IMAD, 2016_[4]). In 2015 the dependency ratio of older people is 27.8% of the working-age population. According to the main scenario of the EUROPOP2013, the proportion of elderly people could exceed the size of the working age population by 2060 (IMAD, 2016_[4]).

60. **The unemployment rate (6.4% in 2017) has dropped since 2013 but remains above the pre-crisis level** (Figure 1.3 Panel A). Unemployment rates are relatively high for

¹ According to the main scenario of the EUROPOP2013 (projection made by Eurostat in collaboration with national statistical offices).

both young (13% in 2016) and older workers (6.5% in 2016). Slovenia's unemployment trends are lower or similar to the EU average but above OECD average. Long-term unemployment remains an issue (Figure 1.3 Panel B). Half of all jobless workers have been unemployed for more than a year (OECD, 2017_[11]) and more than 40% of long-term unemployed are older than 50 (European Commission, 2017).

Figure 1.3. Unemployment, in particular long-term, is a challenge

Source: OECD.

61. **Slovenia lags behind more developed economies in terms of productivity.** Slovenia experienced very strong labour productivity and per capita GDP growth before the global financial crisis. However, per capita GDP levels remained flat in the years after the downturn, as productivity growth slowed and labour utilisation declined (OECD, 2017_[5]). In 2015 productivity was around one fifth lower than the EU average (IMAD, 2017_[6]). This reflects the impact of the crisis and the collapse of domestic demand, depressed capital investment, production factors misallocation in addition to significant regulatory and competition barriers.

1.2. Disposable income inequality is low

62. **Market income inequality has increased in Slovenia, following international trends.** The Gini coefficient of market income (before taxes and transfers) increased to 0.46 in 2015, up from 0.42 in 2008. Market income inequality in Slovenia is higher than in Poland, Hungary or the Slovak Republic, but lower than in Austria, Germany, and Italy (Figure 1.4).
63. **Generous tax provisions and benefits lower inequality considerably.** Benefits and tax reliefs for dependent children, students and for low income households lower inequality considerably. The Gini coefficient for inequality in disposable income (i.e. after taxes and transfers) fluctuates around 0.25 which places Slovenia in the list of the most equal countries of the OECD. This reflects both the design of the tax system and the orientation of the public policy towards generous transfers which support the purchasing power of low income households.

Figure 1.4. The Slovenian tax and transfer system reduces inequalities strongly

Source: OECD Income Distribution and Poverty Database.

64. **Over 740,000 employees earn EUR 14.6 billion in gross income and pay EUR 6.8 billion in PIT and SSCs** (Table 1.1). Employees in the bottom decile earn 2.4% of all income and pay 0.1% of all PIT and 2.0% of all PIT and SSCs combined. Those in the top decile earn 27% of all gross income in 2016 (approximately the same percentage as in deciles 1 to 5 combined), and contribute to 44% of PIT and 30% of all PIT and SSCs combined. Employees in the top 1% earn 6.5% of all income and contribute to 13% of all PIT and 7% of all PIT and SSCs.
65. **Concentration measures suggest a relatively equal income distribution in Slovenia.** The gross income earned by the top 20% of employees is 5.7 times greater than the gross income earned by the bottom 20%, as shown by the S80/S20 quintile share in Table 1.1. Similarly, the S90/S10 inter-decile range shows that gross incomes earned by the top 10% are 11.3 times greater than those earned by the bottom 10%. For disposable incomes, the two ratios are smaller at 4.6 and 8.8 respectively.
66. **The distribution of disposable income in Slovenia is more equal than in many other European countries.** According to the results of the OECD income distribution database (IDD), which is based on survey data in contrast to the tax return data which is at the core of the analysis in this report², the S80/20 ratio of disposable incomes in Slovenia is 3.7, which is similar to the Slovak Republic and the Czech Republic. However, S80/20 ratios are higher in Austria, Germany, Hungary, Italy and Poland.

² Important differences between survey and tax return data exist; for example, the quality of survey data might be less strong at the top of the income distribution because of under-reporting of income, while tax return data is typically less representative at the bottom of the income distribution as it does not fully capture taxpayers who receive benefits.

Table 1.1. The distribution of income earned by employees and the PIT and SSCs they pay in Slovenia

Employee shares of income, PIT and SSCs, by decile, 2016

| | Taxpayers (number) | Gross income | Disposable income | PIT | PIT & Employee SSC | PIT & Total SSCs |
|---------------------------|-----------------------|-----------------|----------------------|--------------|--------------------------|---------------------|
| Total (EUR millions) | 741,670 | 14,629 | 9,992 | 1,685 | 4,637 | 6,775 |
| Bottom decile | 74,167 | 2.4% | 2.8% | 0.1% | 1.6% | 2.0% |
| 2 | 74,167 | 5.0% | 5.7% | 0.7% | 3.5% | 4.1% |
| 3 | 74,167 | 5.8% | 6.3% | 2.4% | 4.6% | 5.0% |
| 4 | 74,167 | 6.6% | 7.1% | 3.9% | 5.7% | 6.0% |
| 5 | 74,167 | 7.6% | 8.0% | 5.2% | 6.8% | 7.1% |
| 6 | 74,167 | 8.8% | 9.0% | 6.8% | 8.2% | 8.4% |
| 7 | 74,167 | 10.1% | 10.3% | 8.8% | 9.8% | 9.9% |
| 8 | 74,167 | 12.0% | 12.0% | 11.7% | 12.1% | 12.1% |
| 9 | 74,167 | 14.7% | 14.4% | 16.3% | 15.5% | 15.3% |
| Top decile | 74,167 | 26.9% | 24.5% | 44.1% | 32.3% | 30.0% |
| Top 1% | 7,416 | 6.5% | 5.8% | 13.0% | 8.1% | 7.2% |
| S80/S20 quintile share | | 5.7 | 4.6 | 83.1 | 9.5 | 7.5 |
| S90/S10 inter-decile | | 11.3 | 8.8 | 703.0 | 20.7 | 15.3 |

Note: For the purpose of this analysis, disposable income is calculated as gross income less PIT and employee SSCs. These measures are calculated on an unequivalised basis at the individual taxpayer level rather than on an equivalised basis at the household level, which is commonly used in household surveys. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

67. Transfers reduce poverty but the share of the population that risks of falling of poverty remains high. 24.3% of population is at-risk-of-poverty before transfers in 2016 in Slovenia, similarly to the EU average (25.9%) (Eurostat). The share of population at-risk-of-poverty after transfers is reduced to 13.9% (17.3% for the EU average). However the elderly remain the most vulnerable population: the at-risk-of-poverty rate for elderly people over 65 years old is above the EU average before and after social transfers (including pensions). Almost 14% of them are at a persistent risk of poverty, which is among the highest in the EU.

1.3. The tax-to-GDP ratio is relatively high and the tax mix is somewhat unbalanced

68. The tax-to-GDP ratio reached 37.0% in 2016, higher than the OECD average (at 34.3% of GDP) but lower than the EU average (at 40% of GDP) (Figure 1.5). Without social security contributions it represents 22.1% of GDP (Ministry of Finance, 2018^[7]), which is lower than the OECD (25.1% in 2014) and the EU averages (26.9% in 2015) (OECD, 2016^[8]) (European Union, 2017^[9]). After a slight decrease in the years following independency, the tax-to-GDP ratio has remained relatively constant over time. In 2016, EUR 14.2 billion were levied in tax (35.2% of GDP) (Figure 1.6).

Figure 1.5. The tax-to-GDP ratio in Slovenia is relatively high

Source: OECD Revenues Statistics.

Figure 1.6. In 2016, Slovenia collected EUR 14.2 billion in tax revenues

Source: (Ministry of Finance, 2018_[7]).

69. **Slovenia's tax mix diverges significantly from the OECD average tax structure** (Figure 1.7). Slovenia's tax structure is tilted towards consumption taxes (14.6% of GDP in 2015) and SSCs (14.5% of GDP) above OECD averages (10.9% and 9% respectively) and EU averages (11.1% and 12%). Taxes on income, profits and capital gains (both of individuals and corporates) represent 6.6% of GDP (below the OECD average of 11.5%). Immovable property taxation stands at 0.6% of GDP in 2016 (1.9% for OECD countries on average). Slovenia levies relatively high environmentally-related tax revenues (4% of GDP in 2016 compared to 1.6% in OECD countries on average in 2014). Over time Slovenia started relying progressively more on taxation on goods and services, and less on taxation on income, profit and capital gains. This contrasts with OECD countries that experienced an increase in income, profit and capital gains taxation since 2008.

70. **Slovenia's tax mix is relatively harmful for economic growth.** Taxes can be grouped based on their potentially distortive effects on growth (OECD, 2010_[10]). Less distortive taxes include consumption taxes (which are very high in Slovenia), recurrent taxes on immovable property and inheritance taxes (which are very low in Slovenia), while the CIT, the PIT, SSCs, and taxes on financial and capital transactions tend to be more harmful for economic growth. In Slovenia, the sum of the more distortive taxes accounts to 60% of total tax revenues in 2016.

Figure 1.7. The tax mix is tilted towards consumption taxes and SSCs (2015)

Source: OECD Revenues Statistics; Taxation trends in the European Union 2017.

1.4. Government expenditures have declined but ageing-related costs might reverse this trend

71. **Since 2010 public spending as a share of GDP has been progressively reduced.** In 2010, public expenditure accounted for 46% of GDP (Figure 1.8). Public spending has been reduced to 41% of GDP in 2016 as a result of consolidation efforts, lower interest payments on public debt and a drop in public investment (OECD, 2017_[11]).
72. **Pensions constitute the main item of government spending.** Pensions amounted to 26% of total public spending in 2016 (24% in 2010), followed by salaries and social security contributions (23%), and expenditures on goods and services (14%) (Ministry of Finance, 2018_[2]).
73. **Projections show an increase in public expenditure of up to 9% of GDP as a result of the ageing of the population by 2050** (Figure 1.9). The share of people aged 65 years and above will reach 33% by 2050 (Figure 1.11). Pensions could increase to up to 15.6% in GDP by 2050 (11.8% in 2015). Health public expenditures are forecasted to reach 9.4% of GDP (5.2% in 2015), and long-term care 1.9% of GDP (0.9% in 2015). The ageing of the population will not only increase public spending but it will also put tax revenues under pressure, as is described in Box 1.1.

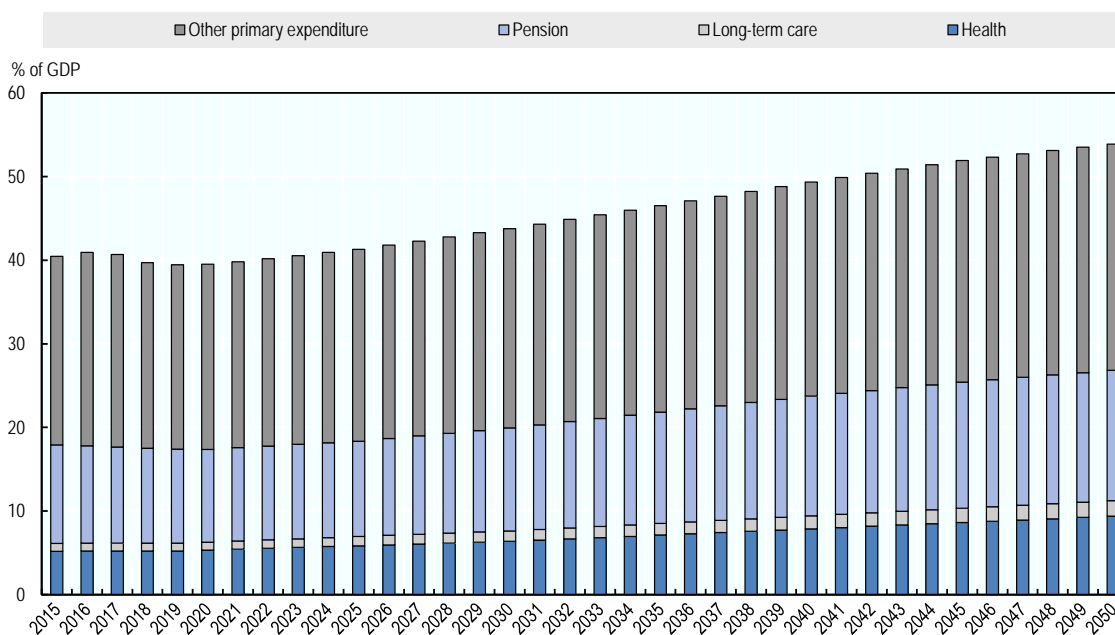

Figure 1.8. Public expenditure as a share of GDP has decreased strongly

Note: Other: payments to the EU budget, capital transfers, capital expenditures, other current transfers and subsidies.

Box 1.1. Impact of ageing on the PIT and SSCs revenues in Slovenia

The working age population currently pays the vast majority of the PIT and SSCs in Slovenia. Therefore, the projected decline in this cohort, alongside a rise in older workers will have significant negative consequences for the revenues raised from PIT and SSCs in the coming decades.

The Slovenian old-age dependency ratio is set to rise sharply from 18.7% in 2016 to 25.2% in 2030 and 28.3% in 2040 (European Commission, 2017^[9]). Over the same period, there is an expected decline in the working age population from 66.4% in 2016 to 61.0% in 2030 and 58.2% in 2040. In the taxpaying population, those of working age pay 97% of all PIT, 99% of all employee SSCs and 90% of all employer SSCs (the small amounts of PIT and SSC remaining are paid by those aged over 65).

By applying the projected population changes by age group (in percentage points) to the number of taxpayers in the same age groups in the taxpayer population it is possible to estimate the PIT and SSC loss associated with aging over the period. This assumes that population changes will correspond to the taxpaying population, that average PIT and SSCs by age group remain constant over the period and stable population growth to 2030. According to the analysis, the PIT could fall by over 9% and employer and employee SSCs by over 6% and 11% respectively by 2040 (Figure 1.10). These Exchequer declines represent 1.6% of GDP.

Figure 1.10. The impact of ageing could be significant on the PIT and SSCs revenues in Slovenia

Note: The European Commission 2018 Ageing Report projects that those aged 0 – 14, 15 – 64 and 65 and over will change (in percentage points) between 2016 and 2040 by -1.3%, - 8.2% and 9.6%. Note that total PIT and SSCs in microdata do not match exactly to PIT and SSCs reported by the Ministry of Finance of Slovenia.

Methodological information on the microdata is available in the annex.

Note: Figures for 2020-2050 are projections based on the medium-fertility assumption (total fertility in all countries is assumed to converge eventually toward a level of 1.85 children per woman).

Source: United Nations, World Population Prospects: The 2017 Revision.

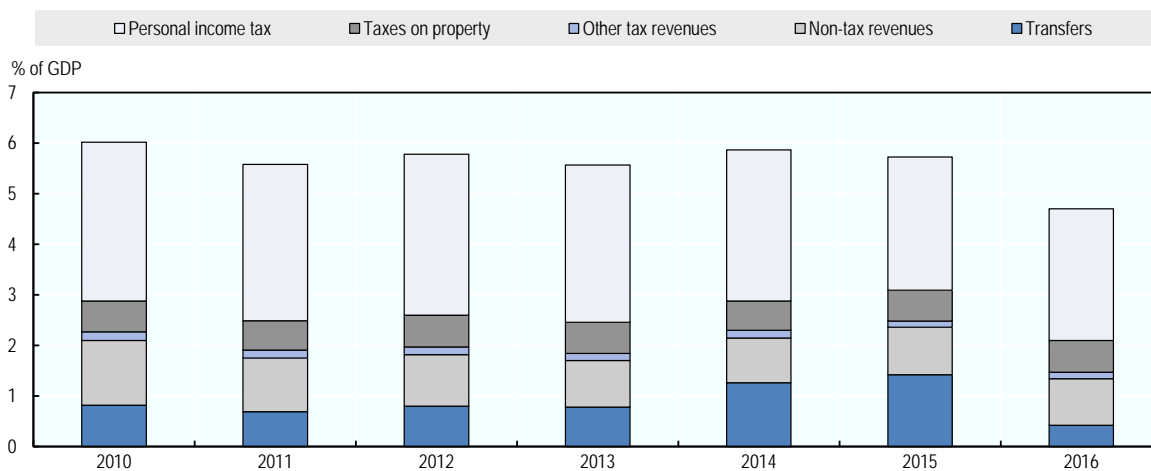

1.5. Local governments rely on revenues from the PIT and property taxes

74. Revenues of municipalities consist for a large part of tax revenues; non-tax revenues and equalisation grants constitute the other, although smaller, sources of local financing. Tax revenues constitute 71% of the total revenues for local governments.

Revenues from the central government's PIT are shared with local governments. The Financing of Municipalities Act stipulates that 54% of PIT revenues collected by central government are shared with municipalities. Property tax revenues constitute 13.5% of total local revenues (Figure 1.13), which is low in international comparison. Other local tax revenues include revenues from certain taxes on goods and services and from the inheritance and gifts tax, a tax on real estate trading, the local tourist tax and a gambling tax (Ministry of Finance, 2018_[2]). Non-tax revenues including local contributions, fees, fines, concession fees, revenues from assets and grants constitute 20% of local tax revenues.

75. **Equalisation transfers to local government amount to 8.9% of total local revenues in 2016** (Ministry of Finance, 2018_[2]). Municipal financing is based upon the principles of “adequate spending” and “adequate funding” (OECD, 2011_[13]). The level of “adequate spending” is estimated every year through a formula taking into account the functions devolved to municipalities and a number of demographic, geographic and development criteria, which vary across municipalities. The “adequate funding” principle aims at matching the financial resources of municipalities with the level of “adequate spending”. So, each year, the Ministry of Finance determines the exact amount of PIT revenues that will be shared with each municipality, where the total amount that is shared equals 54% of total PIT revenues. If revenues from the share of the PIT and own taxes are not sufficient to cover a municipality's spending needs, the municipality can request additional funds from the central government in the form of equalisation transfers.
76. **Revenues from local governments have dropped significantly from 6% of GDP in 2010 to 4.7% in 2016.** There are two main explanations. First, the significant reduction in PIT revenues for municipalities in 2016 is a result of the drop in central government PIT revenues after the economic crisis; there is a 2 year gap between the collection of PIT revenues by central government and the sharing of those revenues with the municipalities. As a result, the impact of the crisis has hit municipalities with a delay. Second, there has been a reduction in the transfers received from the European Cohesion Fund (Ministry of Finance, 2018).

Figure 1.13. Local government rely strongly on revenues from the PIT and a lot less on revenues from property taxes

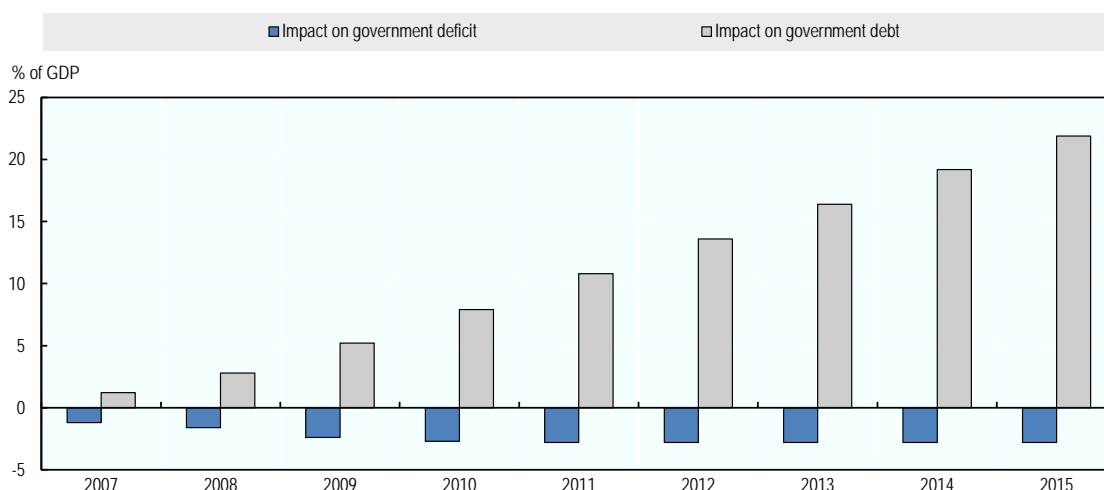

Source: Ministry of Finance of Slovenia, Bulletin of Government Finances 1/2018, January 2018.

1.6. Slovenia faces a window of opportunity for a comprehensive tax reform

77. **There is a momentum for a fundamental tax reform in Slovenia.** The business cycle was strongly impacted by the 2008 and 2013 crisis, with the output gap³ falling to -5.5% of potential GDP in 2013 (OECD, 2017^[14]) (IMF, 2017^[3]). Slovenia is currently closing the output gap⁴ (Ministry of Finance of Slovenia). With the annual growth rate expected to gradually converge to 1¾–2%, Slovenia could take advantage of this period of favourable economic growth to undertake a significant tax reform.
78. **A comprehensive tax reform will have to be (at least) budget neutral and be aligned with the country's fiscal rule.** Over the past two decades, Slovenia has undertaken a number of extensive reforms. Box 1.2 describes the most recent tax reforms in more detail. Some of these reforms – in particular the comprehensive reform in 2006-07 – were not fully funded, creating significant budget deficits. The 2006-07 tax reform reduced the number of PIT brackets from 5 to 3, reduced the top PIT rate and increased the general tax allowance. The payroll tax was gradually abolished and the CIT rate was gradually reduced. The 2006-07 tax reform strongly lowered tax revenues, resulting in an increased budget deficit and government debt (Figure 1.14).

Figure 1.14. The 2006-07 tax reform in Slovenia significantly lowered tax revenues and increased government debt with over 20%

Source: Ministry of Finance of Slovenia.

79. **The upswing in economic activity and growth should be used to lower public debt.** Compliance with both the national fiscal rule (balanced government budget in the medium run, without long-term borrowing), and the medium-term objective of the EU fiscal framework (surplus of 0.25 % of GDP⁴) should remain the objective. In fact, the European Commission has recently noted that Slovenia's medium-term objective is not

³ The output gap refers to the difference between actual and potential gross domestic product as a percentage of potential GDP.

⁴ The medium-term objective corresponds to a balanced budget to be achieved in 2020, within the stability programme horizon.

planned to be achieved by 2021, which indicates that Slovenia might have to increase its tax revenues (European Commission, 2018_[15]).

Box 1.2. Summary of the tax reforms in Slovenia since 2005**2005**

- After debate about a flat personal income tax, decision not to implement a flat personal income tax with a flat rate of 20% levied on taxable income net of a basic tax allowance.
- Adoption of a dual income tax system with the introduction of schedular taxation of interest, dividends and capital gains at a single rate of 20% (with effect as of 1st January 2006)
- Replacement of the grossing up mechanism used to calculate the PIT on pensions by a special pensioner allowance (tax credit)
- Progressive tax schedule with 5 tax brackets with marginal tax rates ranging from 16% to 50%
- Gradual abolition of the payroll tax (introduced in 2005, with effect as of 1st January 2006, and a phase out on 31st December 2008)

2007

- Gradual reduction of the CIT rate (from 25% in 2006 to 23% in year 2007, 22% in year 2008, 21% in year 2009 and 20% in year 2010 and beyond)
- Changes in the tax schedule for non-capital income: from 5 to 3 tax brackets (16%; 27%; 41%) with a decrease in the highest marginal tax rate from 50% to 41%
- Increase of the general tax allowance
- Introduction of the additional general tax allowance depending on individual income (2008)
- Increase in the general tax allowance for taxpayers with the lowest income (2010)

2012

- Reintroduction of the 50% PIT rate (as a temporary measure with effect as of 1st January 2013)
- Reduction of the student personal allowance from EUR 3 228 to EUR 2 477 (with effect as of 1st January 2013)
- Increase in the tax rate on interest; dividends and capital gains from 20% to 25% (with effect as of 1st January 2013)
- Introduction of the schedular taxation for rental income with the rate 25% after 10% standardised cost (with effect as of 1st January 2013)
- Introduction of the flat-tax scheme for self-employed and unincorporated business with revenues of up to EUR 50 000 with effect as of 1st January 2013 (extended in 2014 with effect as of 1st January 2015); the same regime was also introduced for micro businesses
- Gradual decrease of the statutory CIT rate: from 20% to 18% in 2012, 17% in 2013, 16% in 2014 and 15% in 2015. However the CIT rate remained 17% from 2013 to 2016)
- Increase of the standard VAT rate by two percentage points (to 22%), and the

reduced VAT rate by one percentage point (to 9.5%) (on 1st of July 2013)

2014 (taking effect as of 1 January 2015)

- Increase of the taxes on insurance premiums and financial services by two percentage points (to 8.5%)
- Introduction of SSCs for students (2015): both employee and employer SSCs for pension and disability insurance (8.85% and 15.5%), employer SSCs for health (6.36%) and employer SSCs for injury at work (0.53%).

2016 (taking effect as of 1 January 2017)

- Increase in the corporate income tax rate from 17% to 19%
- PIT schedule
 - Introduction of an additional tax bracket (34%) for income between EUR 20 400 and EUR 48 000; lowering of the second highest tax rate (from 41% to 39%) for income between EUR 48 000 to EUR 70 907; reinstatement of the 50% PIT rate as a permanent measure
- Increase in the additional general allowance threshold for low wage earners just above the minimum wage (from EUR 10 866 to EUR 11 166)
- Reduction of the taxation on performance bonuses (13th salary): up to 70% of the average wage is exempt from the income tax (up to 100% in 2017) with effect as of 1st of January 2018)
- Introduction of the Act on fiscal validation of receipts

2017 (taking effect as of 1 January 2018)

- Additional general allowance: introduction of a linearly determined additional general tax relief for incomes between EUR 11 166.67 and EUR 13 316.83
- Introduction of a special tax scheme for income from employment of posted employees abroad
- Introduction of anti-avoidance provisions in the flat-tax scheme for the self-employed and micro business (absolute limits to expenses, rule that prevents companies from splitting-up to stay under the flat rate threshold, etc.)
- Increase in the special personal tax allowance for the income from students' work from 70% to 100% of the general allowance.

Chapter 2. Labour market, social policy and tax policy related challenges in Slovenia

The combination of high employee SSCs, employer SSCs and progressive PIT rates results in very high tax burdens on labour income in Slovenia. The tax system increases the labour costs of employers considerably, thereby reducing incentives to hire workers, and, even more strongly, reduces net-take home pay for workers, thereby reducing incentives to participate in the labour market and increase work efforts. High unemployment and inactivity traps exist. Young people enter the labour market late and older workers leave too early. Wages and pensions are low and the wage structure is compressed particularly at the low end of the wage distribution. To compensate for the high tax burden on labour income, Slovenia has put in place many tax exemptions, in particular aimed at low-income taxpayers, families with children and pensioners. High taxes on labour exacerbate existing labour market weaknesses, including low levels of skills, and result in too low labour market participation rates of younger and older workers. As a result, the pension and health funds, which rely predominantly on SSCs, face significant budgetary difficulties. In light of the ageing population, increasing the labour market participation of older workers is a key reform priority.

2.1. The labour tax burden is high but the personal income tax base is narrow

2.1.1. The combined PIT and SSC burden is high in Slovenia

80. **The tax burden on labour income in Slovenia is high because of the combined effect of high employee and employer SSCs and a progressive PIT rate schedule.** Employee SSCs are levied at a rate of 22.1% which is the highest of all OECD countries; on average across the OECD, employee SSC rates are 9.8%⁵. Employer SSCs are levied at a rate of 16.1% in Slovenia compared to a rate of 17.5% on average in the OECD⁶. In addition, the top statutory PIT rate of 50% is high. Slovenia is among the 10 OECD countries where workers earning an “average wage” (AW) – i.e. the gross wage that a worker can earn yearly on average in the private sector – are taxed the most. The average tax wedge⁷ for single workers without children earning an AW was 43% in 2017

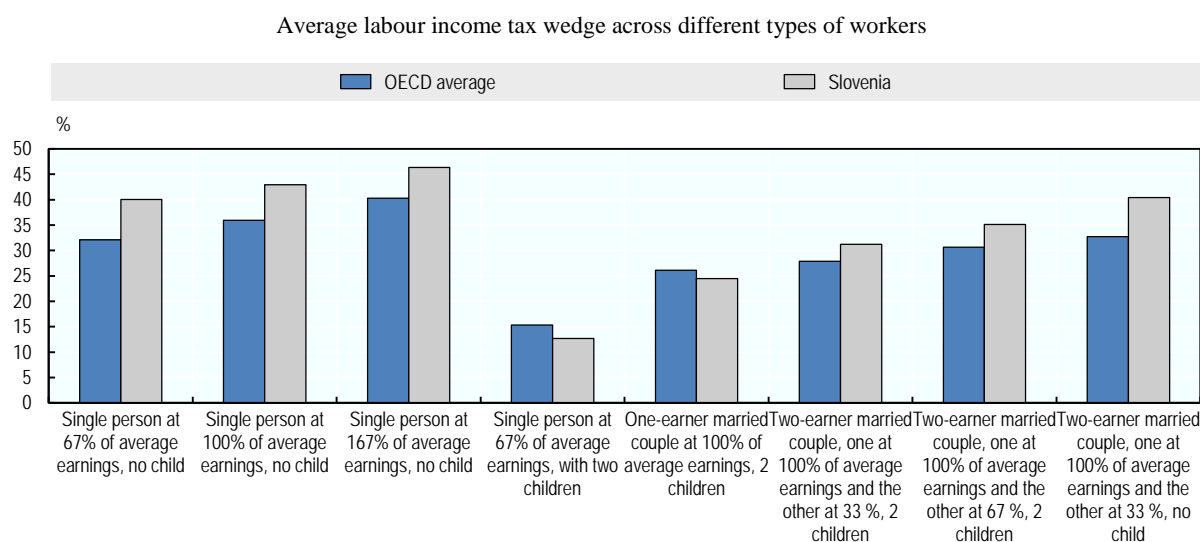

⁵ This figure is the average employee SSC rate for a single person, at the average wage, without children.

⁶ See previous note.

⁷ The tax wedge is the difference between labour costs to the employer and the corresponding net take-home pay of the employee as a percentage of total labour costs. It takes into account personal income taxes, employee and employer SSCs, payroll taxes (if any) net of cash benefits. Total labour costs are the sum of gross wage earnings, employer SSCs and payroll taxes (if any).

compared to 36% on average in the OECD (Figure 2.1). For married couples, the average tax wedge is lower than for single taxpayers but it is still above the OECD average. The tax wedge in Slovenia is below the average tax burden in the OECD only for single taxpayers and one-earner married couples who have two children.

Figure 2.1. The tax burden on labour income in Slovenia is high

Source: OECD Taxing Wages 2018.

81. **High taxes on labour income increase labour costs for firms** (Figure 2.2). Total labour costs are higher in Slovenia than in the Czech Republic, Hungary, or the Slovak Republic because of higher wage levels and employer SSCs. However, total labour costs in Slovenia remain below the levels in Austria and Italy.
82. **A combination of high employee SSCs and PITs reduce the take-home pay for workers considerably.** The net personal average tax rate⁸, which measures the effective employee SSC and PIT burden as a percentage of gross wage earnings, is particularly high for single workers without children. For this category of workers, Slovenia is in the top 5 of OECD countries with the highest personal average tax rate (33.7%), after Belgium, Germany, and Denmark. The tax burden is higher in Slovenia than in the some selected East European countries (the Czech Republic, the Slovak Republic) at all income levels (Figure 2.3). Despite a higher tax burden than in the selected East European countries, workers in Slovenia take home more pay after tax because of the higher level of the AW (Figure 2.4). However the net-take home pay in Slovenia is significantly lower than in Austria reflecting higher wages and a less burdensome tax system.

⁸ The net personal average tax rate is defined as the sum of personal income taxes and employee social security contributions net of cash benefits expressed as a percentage of gross wage earnings.

Figure 2.2. Total labour costs are higher in Slovenia than in other East European countries

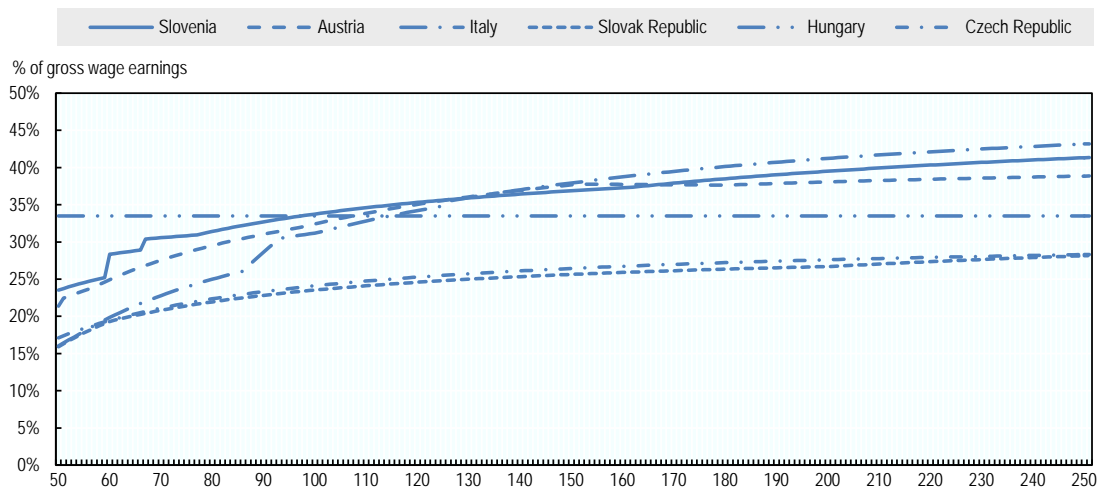

Total labour costs (in EUR) of employing single workers without children at different income levels, by % of the AW

Source: OECD Taxing Wages 2018.

Figure 2.3. The net personal average tax rate in Slovenia is high

Single worker without children, by % of the AW

Source: OECD Taxing Wages 2018.

Figure 2.4. Workers in Slovenia take home more pay than in other East European countries

Source: Taxing Wages 2018.

83. The combined effect of employee SSCs and PITs in Slovenia remains progressive.

Despite of the large share of employee SSCs which are levied at flat rates, the overall average effective tax rate (which is the joint employee SSCs and the PIT) for single taxpayers is significantly increasing with income; i.e. statutory PIT and SSC progressivity remains relatively high⁹. Over the 50-250% of the AW income range, the AETR increases by 0.085 percentage point for each percentage point increase in the income level. This is above Austria (0.079 pp), the OECD average (0.074 pp), the Slovak Republic (0.047 pp), the Czech Republic (0.045 pp) and Hungary (0 pp), but lower than in Italy (1.04 pp). However, the progressivity of the tax system in Slovenia is below the progressivity on average in the OECD and comparative countries for families with children despite of the generous child tax provisions.

2.1.2. Generous tax provisions narrow the PIT base considerably

- 84. Tax allowances narrow the PIT base considerably and come at a high cost in terms of tax revenue foregone.** Slovenia implements a wide range of tax allowances, including a general allowance, personal allowances, allowances for dependent family members, and other income-specific allowances. Pensioners benefit from a PIT credit. Overall, the PIT allowances and credits come at a cost in terms of tax revenue foregone of 4.75% of GDP in 2016 (Table 2.1).

⁹ Similar results are observed when taking into account the PIT only.

Table 2.1. Tax allowances in Slovenia in 2016

| | % of taxpayers claiming | Amount (millions EUR) | Amount (% of GDP) |
|--|-------------------------|-----------------------|-------------------|
| General allowance | 95.33 | 1 038.29 | 2.61 |
| Additional general tax relief for low income* | 54.54 | 282.55 | 0.71 |
| Personal allowance | | | |
| <i>For disabled person</i> | 0.27 | 1.92 | 0.0 |
| <i>For student</i> | 6.25 | 20.49 | 0.02 |
| For dependents | 26.17 | 304.14 | 0.76 |
| Other | | | |
| <i>Special deduction for voluntary additional pension insurance payments</i> | 3.56 | 7.25 | 0.02 |
| <i>Credit for pensioner (% of pension)</i> | 24.6 | 235.33 | 0.59 |
| Total | | 1 889.96 | 4.75 |

Note: *The additional general tax relief for low income have changed on January 1, 2018.

Source: Ministry of Finance of Slovenia.

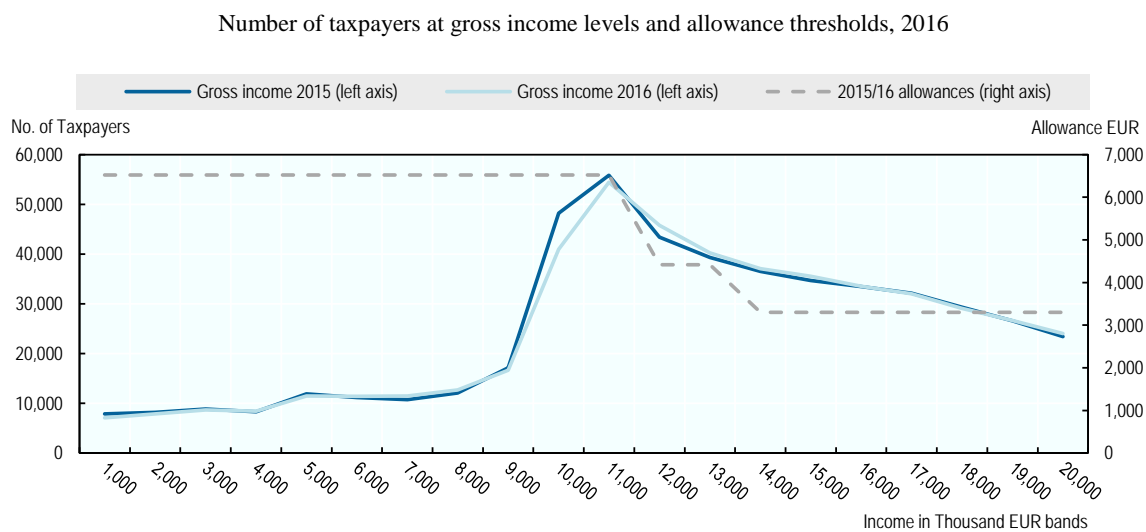

85. **Generous tax allowances offset the impact of the high statutory labour income tax burden in Slovenia.** Slovenia is amongst the OECD countries where labour income tax rates are high but tax bases are narrow. While generous tax allowances could be justified in order to prevent too large distortive effects of the high tax rates, their impact is often selective in that they are targeted at certain taxpayers who benefit more than other taxpayers.
86. **For instance, families with children benefit from very generous tax allowances which reduce the tax burden for families with children significantly.** In 2017, the average tax wedge in Slovenia for one-earner married couples with two children at the average wage is 24.5%, which is significantly lower than the corresponding tax burden for single taxpayers (Figure 2.5). This results in large differences in disposable income across family types. Slovenia is the third OECD country with the highest difference between disposable income for families with or without children.
87. **Until 2018, the allowance system had no taper rate but thresholds.** Figure 2.6 shows the number of taxpayers at gross income levels going up in thousands alongside the general allowance thresholds for taxpayers with low incomes for both 2015 and 2016. Incomes below EUR 10,866 are entitled to a tax allowance of EUR 6,520. As a taxpayer's income increases from EUR 10,866 to EUR 12,571 the allowance is reduced by 32% to EUR 4,419. For incomes beyond this point, the allowance is reduced by a further 25% to EUR 3,303. This allowance structure may produce an economic incentive for taxpayers, and potentially employers, to report incomes below these thresholds before the allowance is reduced. According to the analysis, in both 2015 and 2016, the highest number of taxpayers in any thousand euro band is EUR 10,000 and EUR 11,000, which is just before the most significant loss in the tax allowance. The number of taxpayers continues to fall as the allowance is further reduced in steps. The introduction in 2018 of a linearly determined general tax relief for incomes between EUR 11 166.67 and EUR 13 316.83 might reduce the taxpayers bunching below allowance thresholds in Figure 2.6.

Figure 2.5. Single taxpayers face a much higher net personal average tax rate than families with children

2.2. Too few young and older people are active in the labour market

2.2.1. Labour market participation of both men and women in the prime age category of 25-54 is very high

88. Slovenia's labour market participation rate¹⁰ of workers in the prime age category of 25-54 is 91.9% in 2017, which makes Slovenia the top performer in the OECD (Figure 2.7). The employment rate¹¹ is also amongst the highest (86.1% in 2017), above the OECD (77.8%) and the EU (79.7%) averages. No major differences prevail between the participation of both men and women, which suggests that Slovenia does not face a significant gender gap on the labour market. In addition, part-time work is not widespread. In 2015, only 3% of employed men were in part-time employment (5.3% on average in the OECD). The share is higher for women (8.2%) but still significantly lower than on average in the OECD (22.3%).

Figure 2.7. The participation rate of male and female workers in the prime age category of 25-54 is the highest of the OECD

Source: OECD Labour market statistics.

2.2.2. Labour market participation of young workers is low

89. Labour market participation for youngsters (aged 15-24) drops to 33.7%, much below the participation rate in other OECD countries (47.2% on average) and the EU (42.3%). The weak participation on the labour market is worsened by emigration flows of young skilled workers (see section 2.2.2). The employment rate shows a similar trend (34.8% for Slovenia, against 41.3% in the OECD on average).

¹⁰ Labour market participation rate is defined as labour force divided by the total working-age population, with labour force defined as all persons who fulfil the requirements for inclusion among the employed or the unemployed.

¹¹ Employment rate is defined as employed population divided by the total working-age population, with employed population defined as those aged 15 or over who report that they have worked in gainful employment for at least one hour in the previous week or who had a job but were absent from work during the reference week.

90. **Young workers enter the labour market relatively late.** The duration of study for Slovenian students is relatively long (OECD, 2016_[16]) which can be explained by the fact that students work instead of finalising their degrees. Possibilities are offered to students to work (mainly under temporary work contracts which reduce their future benefit entitlements) and study at the same while benefiting from generous conditions (state-funded tuition fee waivers, subsidies for living expenses such as meals, accommodation, transportation and cultural activities, state scholarships) (OECD, 2016_[16]).
91. **As a result, current younger cohorts have relatively shorter insurance periods than their counterparts in the past.** For example, in 2002, workers aged 30-34 had been insured already for 11 years on average, while in 2015 workers in this age group had been insured for only 8 years on average (OECD, 2016_[16]). Shorter insurance periods will result in lower benefit entitlements for workers in the future (e.g. lower pensions) and reduces revenues for government to finance the welfare spending of the current generation.

2.2.3. Labour market participation of older workers is very low

92. **The labour market participation of older workers is very low.** Only 41.2% of the workers in the age category 54-65 are still active in the labour market. In only two other OECD countries (Luxembourg and Turkey) older workers participate as little as in Slovenia. Similar trends can be observed with the employment rate of older workers. In 2017, only 42.8% of older workers are employed, whereas it is 57% on average in the EU and 60.4% in the OECD. Amongst older workers, low skilled (in particular below upper secondary schooling) leave the labour market earlier than skilled workers.
93. **Older workers retire early.** According to the tax records micro-dataset of the Ministry of Finance of Slovenia, the gap between the official retirement age and the effective retirement age is more than 4 years on average. Slovenia has recently increased the official retirement age to 65 for both men and women by 2020 (from 63 for men and 61 for women)¹². However if the 4-year gap remains, the effective retirement age will still be significantly below the official retirement age (around 61), which is extremely low compared to other countries.
94. **Several factors explain early retirement of older workers.** First, the unemployment insurance system allows older workers to retire earlier (OECD, 2016_[16]). 30% of pensioners used the unemployment system as a bridge to retirement, where unemployment benefits are often higher than the pension the worker will receive (Ministry of Labour, Family, 2016_[17]). Seniority bonuses for older workers can make the hiring of an older worker 15% more expensive than a younger worker (OECD, 2017_[5]), thereby possibly inducing employers to end the contract of their older workers. Sickness leave is also used by older workers as a vehicle to retire early. In addition, before the 2013 pension reform, older workers faced no financial incentives to continue working as an additional year of working was associated with a 4% decrease in net pension wealth (OECD, 2016_[16]).
95. **The 2013 pension reform introduced measures to increase the labour market participation of older workers.** First, the reform ensured that workers will increase their

¹² However, early retirement will still be possible for those with more than 40 years of pension contributions.

pension entitlements if they work longer. Moreover, workers eligible for retirement can choose to continue working under several different arrangements, including: i) working part-time and receiving a proportional pension which is increased by 5% if they are less than 65 years of age; ii) continuing to work full-time and receiving 20% of their pension while they work; iii) receiving a full pension and working via a so-called temporary and occasional work contract, which is subject to social security contributions and an additional 25% duty payable by the employer (OECD, 2016_[10]). Slovenia should evaluate whether the 2013 pension reform is effective in closing the gap between the statutory and effective retirement age, and whether future reforms are needed.

96. **In addition, Slovenia should consider increasing the legal retirement age from 65 to 67**, as recommended in the OECD Economics Surveys: Slovenia 2017. Such a measure could form part of a longer term proposal to lift the retirement age on a prospective basis. Following the direction taken by the 2013 pension reform, Slovenia could consider additional (tax and non-tax) reforms which smoothen the transition from work to retirement, such as part-time work and part-time retirement.

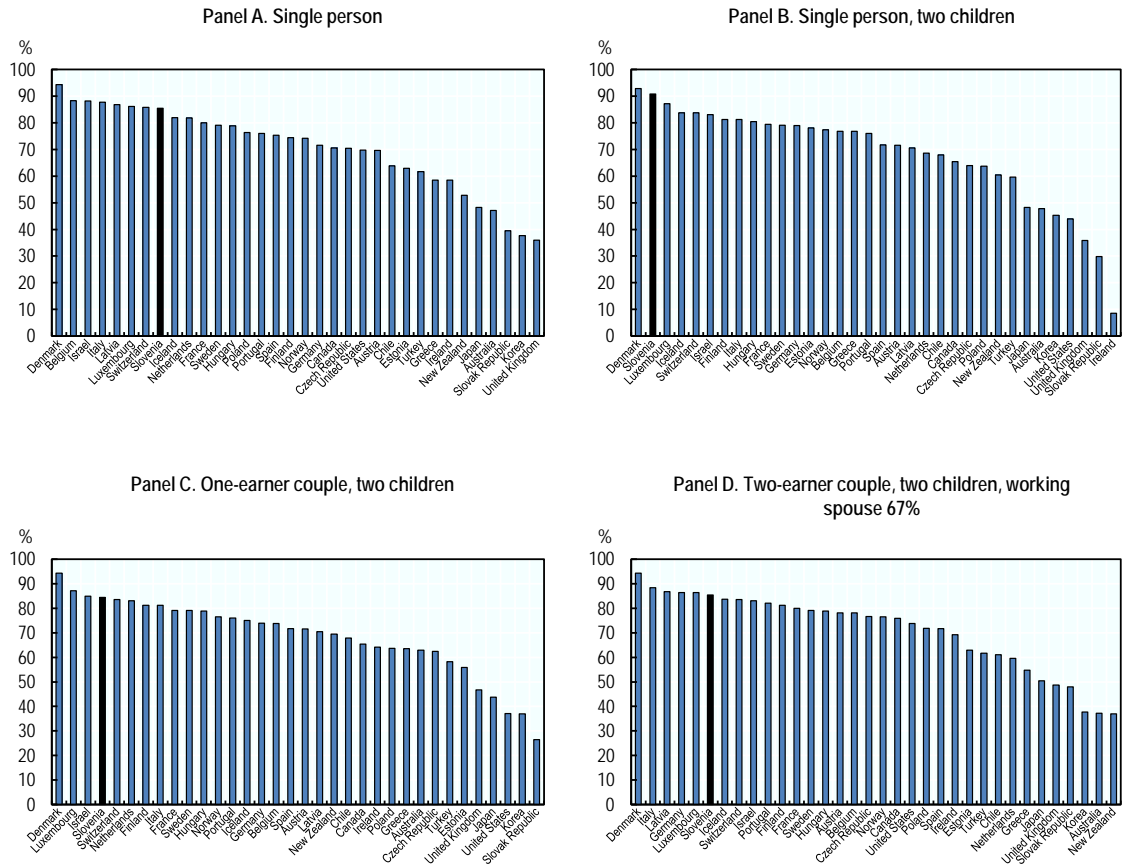

2.2.4. Significant unemployment and inactivity traps exist

97. **Participation tax rates (PTRs) are high in Slovenia.** Participation tax rates¹³ measure how much of the increase in gross earnings is taxed away when individuals enter the labour market from short-term unemployment into full-time work (Figure 2.8). Therefore high participation tax rates reflect that the tax and benefit system does not encourage unemployed workers to join the labour market.
98. **High PTRs are explained by the loss in unemployment benefits when workers enter the labour market and because of the high SSC burden levied on their wage earnings** (Figure 2.9). The latter does not show up in the chart as unemployment benefits are also taxed with employee SSCs. PTRs from long-term unemployment into full-time work (inactivity trap) are also high, especially for lone parents and one-earner married couples with children. The loss of social assistance and the payment of SSCs are the main drivers of inactivity traps.
99. **Reducing both unemployment and inactivity traps is particularly important given the ageing of the population in Slovenia.** Higher degrees of labour market participation will prevent that people fall into poverty and will increase the revenues from social security contributions, which can help addressing the rising age-related public expenditures. Different options are available to stimulate unemployed or inactive workers to re-enter the labour market, including a reduction in employee SSCs and the use of targeted into-work benefits. For instance, individuals who re-enter the labour market after a period of inactivity could receive, for a pre-set period of time, an additional into-work benefit equal to a fixed percentage of their previous unemployment or social assistance benefit. However, an in-depth discussion of the design of these into-work benefits goes beyond the scope of this report.

¹³ Participation tax rates (PTRs) are used to investigate the financial disincentive to move into work. They show how much of the gross income earned from moving into work from either unemployment or inactivity is “taxed” away in the form of lost out-of-work benefits, reduced income-tested benefits, and taxation of in-work income.

2.3. Low levels of skills have a negative impact on productivity

100. **Adults skills levels are low** (OECD, 2017_[5]). Almost one-third of the working-age population (around 400 000 adults) in Slovenia, and in particular older workers, have low levels of literacy and/or numeracy proficiency. Slovenia has achieved a great improvement in skills across age cohorts: around 94% of 25-34 year-olds have completed at least upper secondary education, a figure which is higher than almost all other OECD countries. The percentage of young adults in Slovenia with tertiary education rose from 25% in 2005 to 41% in 2015, exceeding the EU 2020 target of 40%. However, average literacy scores for 25-34 year-olds (including tertiary graduates) are lower than for their counterparts in other countries in the Survey of Adult Skills (PIAAC).

101. **Slovenia's lack of skills is exacerbated by the increasing share of highly skilled people which leave the country. Nevertheless Slovenia is not experiencing a genuine brain drain** (OECD, 2017_[5]). Of the 15 500 adults who emigrated from Slovenia in 2016, 22% were adults with tertiary education. However, this figure has almost doubled between 2011 and 2016, possibly reflecting the impact of the economic crisis. In addition, the share of young (aged 20-29) highly skilled emigrants has increased (from 18% in 2011 to 35% in 2015) possibly driven, among other things, by better socio-economic opportunities including higher wages and lower taxes abroad. This reduces the availability of highly skilled workers for the Slovene labour market and reduces the return on public investment in education for the country (OECD, 2017_[5]). The skills challenge is reinforced by the daily work-home commute to neighbouring countries (Italy, Austria) and the low attraction of foreign highly-skilled workers (16% of immigrants in 2016).

102. **The low skill level lowers productivity and growth.** Skills are central to country's economic prosperity (OECD, 2017_[5]). Making more effective use of people's

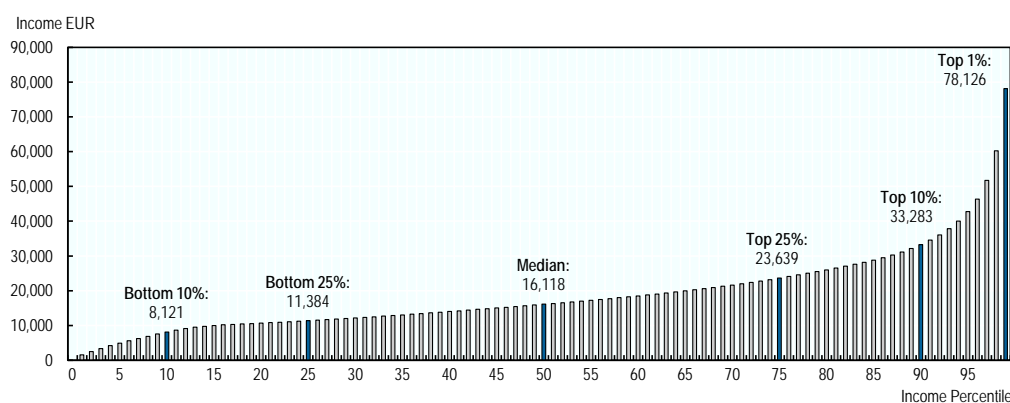

skills in workplaces can boost labour productivity: after accounting for differences in skills proficiency, the use of reading skills explains a considerable share (26%) of the variation in labour productivity across countries (OECD, 2016_[18]).

2.4. Wages are relatively low and the income distribution is narrow

103. **The level of wages is relatively low.** In 2016, mean and median incomes are EUR 19,725 and EUR 16,118 respectively (OECD calculation based on Ministry of Finance of Slovenia tax records microdata) (Figure 2.10). The top 10% and 1% thresholds are EUR 33,284 and EUR 78,126. The low wages have implications on the amount of the PIT that is raised and of SSCs that can be collected. The gap is significant when compared to neighbouring countries such as Italy (EUR 30 642), Germany (EUR 47 809) or Austria (EUR 44 409). However, compared to Central and East European members of the OECD, Slovenia has become a relatively high-wage economy (OECD, 2017_[11]). In 2016 the average annual wage was EUR 18 292 which is higher than in Hungary, Poland, the Czech Republic or the Slovak Republic.

Figure 2.10. Wages are relatively low across the entire wage distribution

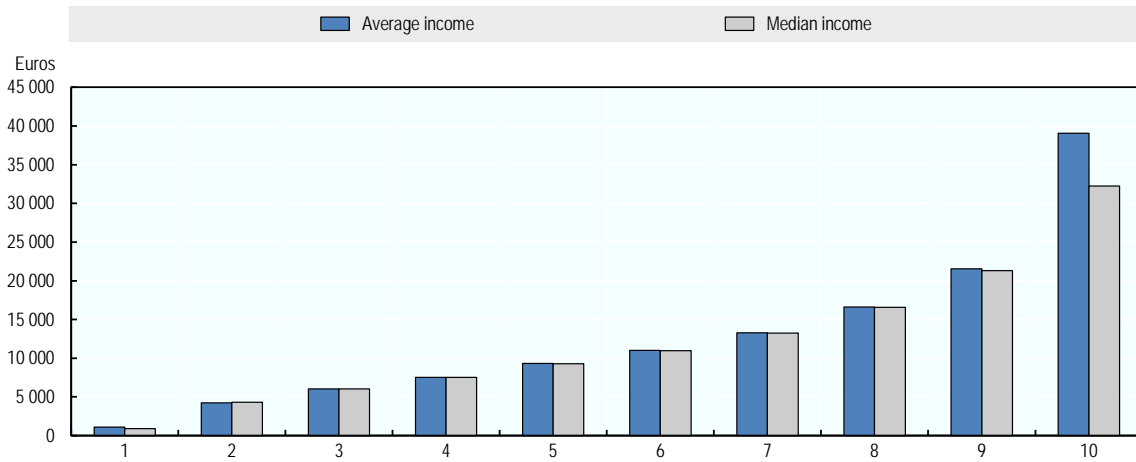

Employee gross income distribution, by percentile, 2016

Note: Taxpayers are employees as defined (that is, those with salary income plus some small self-employment income). Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

104. **Slovenia has a compressed wage structure at the low end of the wage distribution** (OECD, 2017_[11]). Average and median wages are similar across income deciles distribution (Figure 2.11). In Slovenia in 2016, the top employee decile earns 26.9% of all gross income and 24.5% of all disposable income, while the lower employee decile earns 2.4% and 2.8% respectively (Table 1.1). Almost half (45%) of taxpayers earn the minimum wage and 65% of people in paid employment earn below average gross earnings (Statistical Office).

Figure 2.11. Average and median wages are very similar across income deciles distribution

Note: A decile represents 151 729 taxpayers.

Source: Ministry of Finance of Slovenia data.

105. **Pensions are very low in Slovenia.** Figure 2.12 presents the distribution of income for pensioners – defined as taxpayers who receive pension income and, possibly, other types of income – and “full” pensioners, which are defined as pensioners who, besides their pension income, do not have any other source of wage or business income. For most of the distribution, the two groups have similar earnings: the median income for pensioners and full pensioners equals EUR 7,716 and EUR 7,479, respectively. Pensioners who have another source of income (7% of pensioners) increase their earnings. This applies in particular to the higher end the income distribution; after the 75th percentile pensioners start to become significantly better-off due to their additional income sources from employment and self-employment. For the top 10%, full pensioners earn EUR 13,351 which is well below the gross earnings of EUR 15,003 for all pensioners together (so including pensioners who have another source of income). For the top 1%, full pensioners earn EUR 25,905 compared to EUR 34,761 for all pensioners.

Figure 2.12. Pensions are very low in Slovenia

Pensioners gross income distribution, 2016

Note: Pensioners are taxpayers with any pension income. Full pensioners are those with only pension income. Methodological information on the microdata is available in the annex.

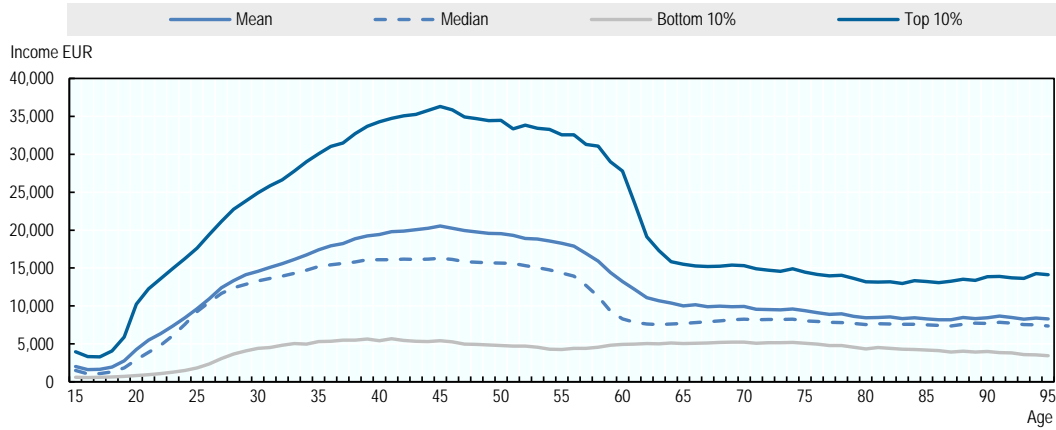

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

106. **Older workers have low stable and relatively equal incomes.** Figure 2.13 shows the gross income distribution of taxpayers aged 15 to 95 in 2016:

- **For young workers**, incomes rise sharply between 20 and 30 years of age in part driven by students, a group also more likely to undertake part-time work, moving from study to employment. For example, at 23 years of age, median incomes are EUR 6,106 and by 30 they have more than doubled to EUR 13,292. Thereafter, median income increases are more gradual reaching EUR 15,220 at 35. The similarity of mean and median incomes across all ages reflects Slovenia's condensed income distribution.
- **For middle-aged workers**, approximately between 35 and 55, median incomes are stable, varying on average (median) between EUR 15,000 and EUR 16,000. The highest incomes are for those aged between 40 and 50. Mean incomes also rise faster than median incomes between these ages indicating a greater level of income inequality, which may partly be attributable to differences in worker productivity.
- **For older workers**, incomes are significantly smaller and income inequality becomes significantly lower, reflected in the closing of the gap between mean and median income after 65 years of age. An extraordinary feature for high earners is the exceptionally steep income cliff as they transition to old age. For example, at age 58, the top 10% of earners have gross incomes of EUR 31,063 but by 64, only a 6 year difference, income among the top 10% have almost halved. This feature is also unusual internationally compared to the Ireland and the US (Kennedy, 2018_[19]) (Auten, Gee and Turner, 2013_[20]).

Figure 2.13. Gross income inequality is higher for workers than for pensioners

Gross income distribution by age, 2016

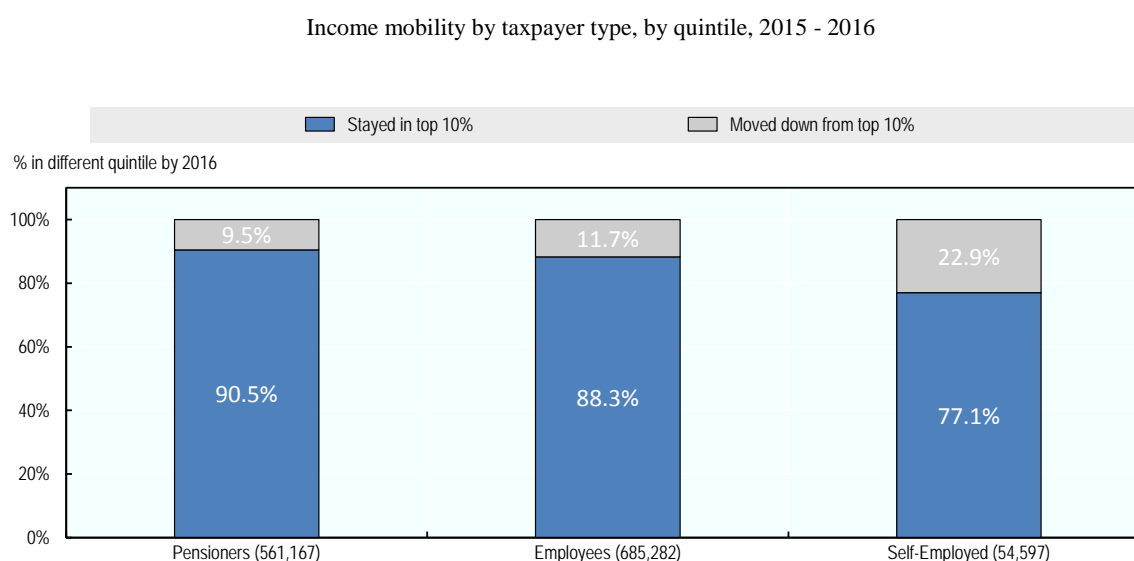

Note: Age data truncated between 15 and 95 for reasons of sample size. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

107. **Pensioner income distribution is very static.** Figure 2.14 examines income mobility in Slovenia by measuring the positional change of different taxpayer groups between 2015 and 2016. The methodology is as follows. A group of taxpayers is identified (for example, employees) and only those observed in both comparison years are retained. In each year, the employee has an origin and destination position in the income distribution. Next, two distinct gross income quintile are calculated in each year. Finally, a transition matrix is calculated across the two years. Figure 2.14 shows the transition probabilities for employees, pensioners and self-employed taxpayers remaining in the top quintile between 2015 and 2016. According to the analysis, of those employees in the top quintile (the top 20%) in 2015, almost 9 in 10 (88%) stayed in that quintile a year later. Of self-employed taxpayers in the top quintile in 2015, 77% stayed in that quintile a year later and 23% moved downwards. Among pensioners, over 90% stayed in the top quintile. Consequently, the highest downward mobility is observed among the self-employed followed by employees and then pensioners.

Figure 2.14. Pensioners in the top of the income distribution are more likely to remain there over time

Note: There are important caveats to consider when interpreting transition matrices. For example, they show relative and not absolute changes in income. They do not capture those who leave the workforce (for example, due to emigration, unemployment or death). In addition, the time horizon is important – this one year transition while illustrative is much more limited and will show less mobility than a transition over a longer time period. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

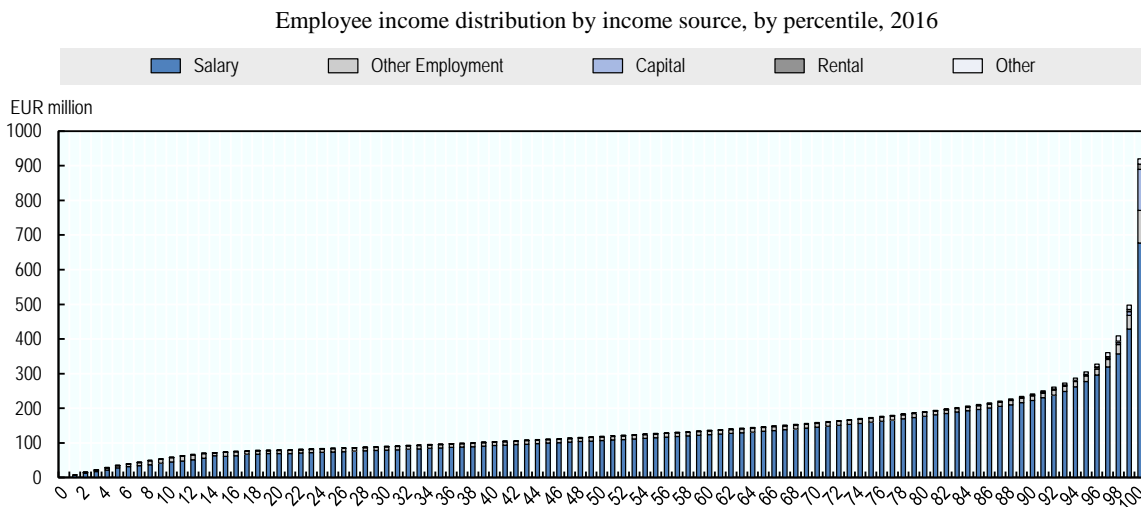

108. **Because wages are low, many taxpayers cumulate jobs.** Taxpayers who have different sources of income are considerably better off.

- For employees, with the exception of the very bottom and top of the income distribution, the analysis shows that salary income comprises the vast majority of gross income (around 90% at most income percentiles). In the bottom decile, salary incomes approximately represent a lower 80% of gross income and this is due to relatively high levels of other employment income, which includes income from holiday bonuses, contractual relationships and student incomes (Figure 2.15). At the top end, and in particular in the top 1% of employee earners, salary represents only 70%. This is due to a high concentration of capital, other employment and rental incomes which comprise 12%, 10% and 2% respectively of total gross income in this top percentile.
- For the first two-thirds of the gross income distribution, pensions comprise the vast majority of all income (above 95%) (Figure 2.16). As pensioners become better-off between the 65th and 85th percentiles, they begin to supplement their income to a greater extent with salary income, other employment income and a small proportion of rental property income, causing the pension proportion of all income to fall to about 80%. Among the top decile of pensioners, salary income increases from a proportion of 15% at the 90th percentile to 39% for the top 1%. Capital income rises more slowly – it comprises 2% at the 98th percentile, 3% at the 99th percentile but 15% in the top 1%. Indeed, the top percentile comprises only 18% of gross income from pensions, the majority comes from salary income

while capital, other employment and property comprise 15%, 14% and 9% respectively.

- Figure 2.17 shows the self-employed and the full self-employed¹⁴ (taxpayer that derive 100% of their income from self-employment) income distribution thresholds by percentile for 2016. In the lower half of the income distribution, the more broadly defined self-employed earn approximately 10 – 15% more on average than the full self-employed. At the median, the self-employed and full self-employed earn EUR 6,732 and EUR 6,732 respectively. After this point however, incomes are significantly higher for the self-employed due to their additional employment income. For example, among the top 10% and 1%, the self-employed earn EUR 23,613 and EUR 64,998 compared to the full self-employed who earn EUR 16,377 and EUR 54,703.
- While self-employment incomes are far lower than employment incomes on average, both income sources follow a broadly similar distributional pattern by age – most income is earned by those aged 35 to 60 (Figure 2.18). Unlike salary income however, self-employment income does not decline as sharply after age 60, suggesting that older taxpayers are more likely to supplement their income with self-employment or the self-employed remain active in the labour market after reaching the age of 60.

Figure 2.15. Towards the end of the employee distribution, the income source diversifies

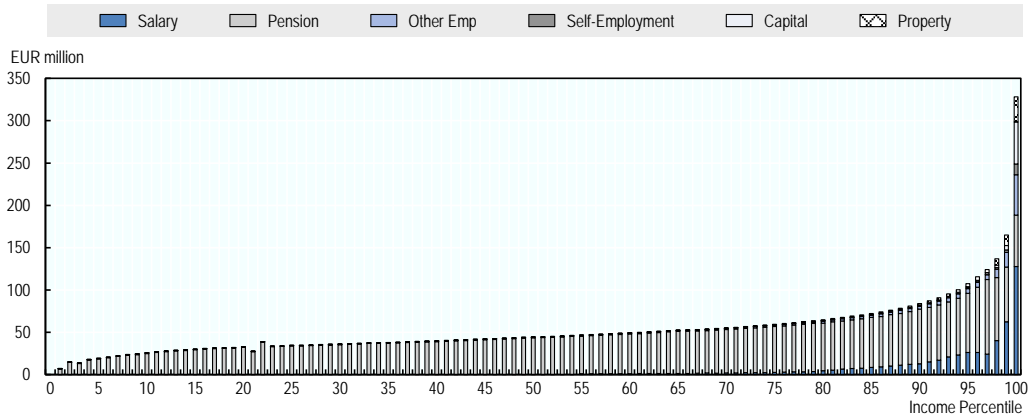

Note: Taxpayers are employees as defined (that is, those with salary income plus some small self-employment income). For the purpose of this analysis, other includes all business, agricultural and other miscellaneous income. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

¹⁴This distributional analysis includes taxpayers in both the flat-rate and actual cost regimes. An analysis examining these regimes separately is presented in Chapter 3.

Figure 2.16. Towards the end of the pensioners distribution, the income source diversifies

Pension income distribution by income source, by percentile, 2016

Note: Taxpayers are pensioners as defined, that is, pensioners with other income sources. Methodological information on the microdata is available in the annex.

Figure 2.18. Unlike salary income, self-employment income does not decline as sharply after age 60

Mean salary, pension and self-employment income by age, in EUR, 2016

Note: Mean averages calculated based on all salary, pension and self-employment income including incomes reported as nil. An analysis done on a median basis shows a broadly similar distribution for salaries and pensions. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

109. **Self-employed are quite mobile.** At the bottom of the distribution, there is greater upward mobility among self-employed, employees and then pensioners (Figure 2.19). For example, 43% of the self-employed moved upwards out of the bottom quintile compared to only 8% for pensioners. Higher mobility among the self-employed is expected and partly reflects the greater risk and returns to business and entrepreneurship. Similarly, pensioners are much more likely to have stable incomes with little income shocks over time compared to employees and the self-employed.

Figure 2.19. The self-employed have the highest upward income mobility from the bottom 20%

Note: There are important caveats to consider when interpreting transition matrices. For example, they show relative and not absolute changes in income. They do not capture those who leave the workforce (for example, due to emigration, unemployment or death). In addition, the time horizon is important – this one year transition while illustrative is much more limited and will show less mobility than a transition over a longer time period. Methodological information on the microdata is available in the annex.

2.5. The welfare system faces financing challenges

2.5.1. The costs of the pension system are rising

110. Pension contributions are not covering all the pension fund's expenditures.

The pension system in Slovenia is a pay-as-you-go system. In 2016 social security contributions amounted to 72% of its total revenues (Ministry of Finance, 2018_[2]). The budget balance was achieved with transfers from the general government (27% from the State budget, social security funds and extra budgetary funds) and non-tax revenues.

111. Several factors are adding pressure on the financing of the pension fund.

Old-age pension transfers to individuals represented 51% of the total pension fund expenditures in 2000 (other expenditures included disability pension, family pension, other types of pensions, current expenditure, salary compensation, transfers to non-profit organisation, etc.) (Ministry of Finance, 2018_[1]). This share has increased to 65% in 2016 reflecting the ageing of the population. Public expenditures on pension are projected to reach 15.6% of GDP in 2050 (11.8% of GDP over the period 2013-15) (OECD, 2017_[21]). Pressure is exacerbated by the relatively low labour market participation on the one hand, and by the low development of the private pension system on the other hand. In its "White book", government explored different options to secure the financing of adequate pensions in the future.

112. Despite of having a minimum pension, pensions in Slovenia remain relatively low increasing the risks for pensioners to fall into poverty (Figure 2.12).

In Slovenia low-income pensioners (20th percentile of the income distribution) are below the poverty threshold (OECD, 2017_[22]). In addition to the general basic allowance, pensioners with

low income can benefit from an additional tax credit equal to 13.5% of the pension received. The cost of this tax credit amounts to EUR 221 million in 2016 (OECD analysis of administrative tax records).

2.5.2. The reform of the public health system is even more urgent

113. **In 2016 health expenditures reached 8.6% of GDP in Slovenia** compared to 9.9% of GDP on average in the EU and 9% in the OECD countries. The health care system is primarily financed by the Health Insurance Institute of Slovenia (HIIS). This is complemented by co-payments spending and voluntary health insurance from three private insurance companies. In 2016 72% of the health financing was from public sources, and 28% from voluntary schemes and households out-of-pocket payments.

114. **Investment in physical capital in the health sector (0.37% of GDP) is low as a share of total government health expenditure, and** is below the OECD average (Figure 2.20). For example, the Czech Republic has a similar amount of government health expenditure but higher investment in physical capital in the health sector (0.52% of GDP). However, these figures should be interpreted with care and much depends on the types of physical investment that is carried out. For instance, changing demographics and disease patterns imply that there will be less need for “bricks and mortar” investment (especially hospitals) and more need for investment in information infrastructure and human capital. The latter type of investment will strengthen the transfer of information among actors, decentralisation and well-coordinated care (including home care) and prevention and self-care. An in-depth evaluation of these issues goes beyond the scope of this report and could be included in an in-depth evaluation of the functioning of the health care system in Slovenia.

Figure 2.20. Given the government health expenditure, Slovenia has relatively low capital investment in the health sector

Note: Only government health expenditure has been considered in the figure and voluntary/out-of-pocket health expenditure has been excluded.

Source: (OECD, 2017_[12])

115. **The health care system financing highly relies on social security contributions.** In 2016 the HIIS revenues were EUR 2.5 billion with 80% coming from SSCs. However, because of the low labour market participation of old and young

workers and because of the ageing of the population, the funding of health care in Slovenia is under increasing pressure.

116. **The proposal for health reform aims at addressing some of the challenges.**

The proposal aims at increasing revenues for the Health Fund through a wide variety of measures, including making the voluntary insurance co-payments compulsory while introducing lower and upper caps. While this reform would increase the financing of the health fund, it would result in even higher SSCs. A new institution would be created to advise the Ministry of Health, and a list of indicators would be compiled on a regular basis to guide health related policy decisions.

Chapter 3. Tackling the challenges to finance the social security system

Slovenia has a well-developed social welfare system which is very successful in reducing inequality. However, the system is financed primarily through social security contributions (SSCs) which are levied at very high rates, in particular for employees. The challenges to finance the welfare system primarily through SSCs are increasing as a result of the ageing of the society. A comprehensive reform of the SSC system is needed and would entail a cut in employee SSCs across all income levels in order to increase labour market participation, in particular for young and older workers, to incentivise people who are inactive to re-enter the labour market, to increase work efforts and to incentivise workers to improve their skills and, as a result, work more productively. The minimum SSC base for workers below 60% of the AW is too high and leads to very large effective statutory employer SSC rates. This minimum SSC base should be abolished, or, if not possible in the short run, lowered to an income level that corresponds more closely to the minimum wage. The SSC system for regular employees and the self-employed could be further aligned, which would require also that they would be entitled to the same benefits, and the link between SSCs paid and benefits received should be evaluated and strengthened. However, this might not be feasible at low income levels as it would result in too high SSC rates at the bottom of the income distribution, as currently is the case. Slovenia should consider broadening the SSC base by limiting the number of different contribution rates and bases, and aligning the treatment of different types of incomes. In order to put the funding of the welfare system on a solid footing without reducing entitlements to social benefits, the reform will need to shift the funding of the pension and health system partly from SSCs towards general taxation. The financing of the health system needs to be strengthened and a wide range of measures are available. An in-depth evaluation of the efficiency of the welfare system, and in particular of the health fund, would be welcome along-side the introduction of measures that put its financing on a more sustainable footing in light of the challenges linked to the ageing of society.

3.1. High social security contributions distort the functioning of the labour market

117. **The tax mix in Slovenia relies heavily on taxes on labour income and, in particular, on SSCs.** The combined rate of employee and employer SSCs is significantly above the average combined rate in the OECD, although it remains lower than the combined rate that is levied in Austria, Italy, the Czech Republic and the Slovak Republic. Slovenia is one of the few OECD countries where the employee SSC rate (22.1%) exceeds the employer SSC rate (16.1%). While the employee SSC rate is the highest of all OECD countries, the employer SSC rate is below the average rate in the OECD (17.75%). It is also much lower than in other East European countries (the Czech Republic, the Slovak Republic, and Hungary) and Italy and Austria (Figure 3.1).

Figure 3.1. High employee but relatively low employer SSCs in Slovenia

Note: For a single person at the average wage without child.

Source: OECD Taxing Wages 2017.

118. **Tax return data confirms the significant revenues raised from SSCs.** Table 3.1 shows total allowances, credits, SSCs and PIT as a share of gross income in 2016. For employees, employer and employee SSCs represent 15% and 20% respectively while PIT represents 12%. The vast majority of SSCs and PIT is paid by workers between 25 and 60, with the highest payments concentrated among workers aged 35 to 50 (Figure 3.2).

Table 3.1. Tax return data confirm high SSC revenues while the PIT base is narrowed through generous tax allowances

| Income, tax and SSCs contributions by taxpayer group, 2016 | | | | | | |
|--|-----------|----------------|---------------|--------------------|------------|-----------------|
| | Employees | Full employees | Self-employed | Full self-employed | Pensioners | Full pensioners |
| EUR millions | | | | | | |
| Labour Costs | 16,767 | 16,260 | 803 | 501 | 5,919 | 4,981 |
| Gross Income | 14,629 | 14,184 | 772 | 495 | 5,452 | 4,611 |
| Allowances | 4,221 | 4,127 | 429 | 343 | 3,557 | 3,312 |
| Credits | 0 | 0 | 0 | 0 | 235 | 221 |

119. **Slovenia has four social security insurance schemes** (Table 3.2). Slovenia levies high SSCs for pensions (including disability) and health insurance, while the contributions for unemployment insurance and maternity leave are low. Among the selected comparison countries, only the Czech Republic and Hungary levy higher pension SSCs. Only France, the Czech Republic and the Slovak Republic levy higher health SSCs (Table 3.3).

Table 3.2. Social security contributions rates

| | Employee (%) | Employer (%) |
|----------------------------------|--------------|--------------|
| Pension and disability insurance | 15.50 | 8.85 |
| Health insurance | 6.36 | 7.09 |
| Unemployment | 0.14 | 0.06 |
| Maternity leave | 0.10 | 0.10 |
| Total | 22.10 | 16.10 |

120. **High SSCs distort the functioning of the labour market.** SSCs are typically levied at flat rates on all labour earnings, in contrast to the PIT which is often levied at progressive rates and exempts a certain amount of income from tax.

- **High employer SSCs increase labour costs for the employer and therefore reduce labour demand.** High employer SSCs are particularly distortive in firms or sectors where skills and labour productivity are low. They are particularly distortive for older workers in Slovenia whose wages are increasing with age. By increasing the labour cost of employing older workers, high employer SSCs strengthen the labour market distortions that arise because of the automatic increase of wages with age irrespective of labour productivity.
- **High employee SSCs reduce labour supply and work incentives,** in particular for individuals with a weaker attachment to the labour market such as low incomes, older workers and second earners (World Bank, 2007_[23]). High employee SSCs significantly lower disposable income of low-income earners, thereby reducing their incentive to participate in the labour market (see Chapter 2). High employee SSCs will also result in lower PIT revenues as employee SSCs are deductible from the PIT base.

121. **In order to put the funding of the social welfare system on a solid footing for the future, Slovenia needs to ensure that as many workers as possible do participate in the labour market and, hence, contribute through taxes and SSCs to the funding of the welfare system.** This may require different types of reforms that aim at maintaining strong labour market participation of the prime age population and work effort for all income levels, as well as more targeted reforms that focus on particular groups, such as youth, low-skilled and older workers.

122. **Slovenia needs to tackle at source the underlying causes of the low labour market participation of young and older worker through a comprehensive labour**

market reform package. Different factors may contribute to the low level of labour market participation of young and older workers. Important factors are the low levels of skills of certain groups of workers, relatively generous benefits for people out of work (in particular compared to the low income that can be earned on the labour market for those workers), generous provisions for students who are active in the labour market, a weak link between social contributions made and benefits received, the fact that the unemployment system can be misused as a temporary means to bridge to retirement, etc.

123. **A cut in employee SSCs will also be a major part of such a labour market reform.** However, the reduction in employee SSCs will reduce the funds received by the social funds and their funding will need to be assured through other revenue sources. In order to put the funding of the welfare system on a solid footing without reducing entitlements to social benefits, the reform will need to shift the funding of the pension and health system partly from SSCs towards general taxation. Moreover, the tax reform will need to go hand in hand with a broader set of reforms, including the reform of the pension and health care systems. The remainder of this chapter discusses a number of reform options, including a shift from employee SSCs towards general taxation or a shift from employee to employer SSCs (sections 3.2 and 3.3). Other reforms include SSC base broadening, unifying the different SSC systems (sections 3.4 and 3.5), and increased spending efficiency (section 3.6).

3.2. Stimulate labour market activity through a cut in the employee SSC rate

124. **The reduction in employee SSCs will need to stimulate labour market participation, work efforts and incentives to work more productively at the lowest possible tax revenue cost.** Different reform options exist. The reduction in employee SSCs could apply to all workers irrespective of their income level or it can be targeted at specific income levels and/or types of workers. In order to maximise the impact on labour market participation, the design of a reduction in employee SSCs will need to be tailored to the specific characteristics of the labour market in Slovenia. The choice for a reduction that applies to all incomes or is more targeted at low incomes or particular groups of workers will also have an impact on the tax revenue cost of the reform.

3.2.1. A cut in employee SSCs is the preferred option over targeted cuts

125. **Given the narrow wage distribution in Slovenia, an employee SSC reduction targeted at low incomes would stimulate labour market participation considerably but would also negatively affect work incentives.** For a tax reduction to be targeted at low incomes, the reduction would need to be tapered out (i.e. reduced) at a particular taper rate over a well-defined income range. The taper rate then augments the marginal tax rates and wedges, which are already high in Slovenia, thereby further increasing the labour market distortions. In order to limit the tax revenue cost, the reduction would have to be tapered out at relatively low income levels. The corresponding increase in marginal tax rates would negatively affect the work incentives of a large share of the working population. Alternatively, the reduction could be reduced at a higher income level thereby lowering the tax burden for more taxpayers and, as a result, stimulate labour market participation more strongly. This would imply a larger tax revenue cost but would be less distortive as the increased marginal tax rates would affect fewer taxpayers.
126. **A reduction in employee SSCs targeted at all income levels would not only benefit low-income workers but also middle and higher-income workers.** High employee and employer SSCs do not only affect low-income workers. Also middle and

higher income workers face a high tax burden on labour income, which negatively affects work efforts, incentives to strengthen skills and work more productively and incentives to continue working when approaching the retirement age.

127. **Because of the narrow wage distribution and the high labour income tax burdens across the entire income distribution, a reduction in employee SSCs for all income levels (and all economic sectors) would be preferred over targeted cuts.** In order to prevent work disincentives for a large share of the population, a targeted cut in employee SSCs would have to be tapered out at relatively high income levels. However, that would imply that extending the cut to all income levels would come at a relatively small additional tax revenue cost. While such a general reduction would increase the overall tax revenue cost, it would prevent further increases in marginal effective tax rates, which are already very high (Figure 4.8). Because employee SSCs are very high and work incentives need to be increased for all (in particular young and older) workers irrespective of their income level, there is a strong policy rationale to apply a reduction in employee SSCs to all income levels.

3.2.2. To distribute the gains of the reform more equally, a cut in employee SSCs has to be accompanied by a reform of the PIT

128. **Lower employee SSCs can increase disposable income considerably but would benefit higher incomes more.** Figure 3.3 presents results for average tax burdens across the 50-200% of the AW income range for a 5.24 percentage point reduction in employee SSCs. For instance, the net personal average tax rate at the average wage drops from 22.1% to 16.9%. At the average wage, the average tax wedge decreases with 3.3 percentage points. Table 3.4 presents results for different reductions in employee SSCs. Overall a cut in employee SSCs increases disposable income. Disposable income increases more for higher incomes, although lower incomes gain more in relative terms. The PIT offsets part of the decrease in employee SSCs because of the increase in taxable income which is taxed under the PIT. Because of the progressivity of the PIT system, the PIT offsets the impact of the cut in employee SSCs relatively more for higher incomes. Nevertheless, higher incomes would still benefit more in absolute amounts from a general cut in employee SSCs. Figure 3.4 focuses on mean disposable income from employment by income decile before and after a five percentage point employee SSC cut, and shows similar results.

129. **The analysis implies that a general cut in employee SSCs might have to be accompanied by PIT reform in order to distribute the gains of the reform more equally.** Table 3.4 presents the impact on disposable income for a cut in employee SSC accompanied by a change in the PIT rate schedule. Results show that a redesign of the PIT rate schedule which leaves the bottom rate unchanged and increases the other rates and installs a top PIT rate of 45% would share the gains in disposable income more equally compared to the baseline story where employee SSCs are cut but the PIT rates are kept unchanged.

Figure 3.3. A cut of 5.24 pp in the employee SSC significantly reduces the net personal average tax rate and the average tax wedge

Note: The simulated values represent a cut in employee SSC of 5.24 pp (from 22.10% to 16.86%).
Source: OECD Taxing Wages 2018.

Figure 3.4. An employee SSC rate cut would increase disposable income across all deciles with greater relative (but not absolute) increases among the lowest deciles

Mean disposable income from employment before and after a five percentage point SSC cut, by income decile

Note: The analysis assumes no behavioural change and linearity from the employee SSC rate reductions. Total PIT and SSC in the microdata differ from figures reported by Ministry of Finance. Employment disposable income is estimated as income from employment less employee SSCs less PIT. Methodological information on the microdata is available in the annex.

3.2.3. A cut in employee SSC leads to a significant loss in revenues the effect of which is partly offset through the broader PIT base

130. A one percentage point cut in employee SSC is associated with a total loss of **EUR 100 million** (loss of EUR 134 million in SSC and an offsetting recovery of EUR 34 million in PIT). Figure 3.5 shows the employee SSC loss and the extent

recovered through PIT associated with reducing the employee SSC rate by consecutive one percentage points from 22.1% through to 16.86%. The employee SSC reduction of 5.24 percentage points (to 16.86%) is associated with a total loss of EUR 519 million. Loosely, just over one-quarter (26%) is recovered through the PIT system. According to the analysis, the SSC and PIT revenue losses in the first bracket are EUR 20 million and EUR 293 million respectively (Figure 3.6). The majority of SSC losses are focused in the first two bracket. In the top three bracket, PIT recovery exceeds SSC losses.

Figure 3.5. The SSC loss associated with an employee SSC rate cut will be partly recovered through the PIT system

Note: The analysis assumes no behavioural change and linearity from the employee SSC rate reductions. Total PIT and SSC in the microdata differ from figures reported by Ministry of Finance. Methodological information on the microdata is available in the annex.

Figure 3.6. PIT recovery could exceed SSC losses in the top three PIT bracket

SSC loss and PIT gain by PIT bracket from reducing the employee SSC rate by 5.24 percentage points to 16.86%, in EUR million

Note: The analysis assumes no behavioural change and linearity from the employee SSC rate reductions. Total PIT and SSC in the microdata differ from figures reported by Ministry of Finance. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

131. **For all the simulated cuts in employee SSC, the greatest amount of PIT is recovered in the third (34%) rate bracket.** Figure 3.7 shows the simulated PIT revenues recovered in each PIT bracket for various reductions in the employee SSC rate (from 22.1% to 16.86%). The extent to which employees move up PIT brackets depends on both the numbers of employees in the bracket and the relative proximity of each employee's taxable income to the next rate threshold. According to an analysis of employee PIT bracket transitions resulting from a one percentage point cut in employee SSCs (to 21.1%), the first bracket would contract by 7,200 employees while the second, third, fourth and top brackets would expand by 4,300, 2,500, 190 and 120 employees respectively. In the first and largest PIT rate bracket, which comprises 50% of all employees, a one percentage point cut in the employee SSC rate would reduce PIT revenues in the bracket by EUR 4 million while increasing them in the second bracket by EUR 13 million, in the third by EUR 18 million, in the fourth by EUR 3 million, and in the fifth by EUR 5 million. By far, the greatest amount of PIT is recovered in the third (34%) rate bracket. This occurs because, given the same one percentage point SSC cut, over 2,500 employees would move up to this bracket and would now pay an average PIT of about EUR 7,000. For the top 50% rate, the same one percentage point SSC cut would add a small number of employees to the top rate bracket, resulting in approximately EUR 5 million in PIT. Similar conclusions can be drawn for the cuts in employee SSC to 20.1%, 19.1%, 18.1%, 17.1% and 16.86%.

Figure 3.7. An employee SSC rate cut is likely to result in the majority of PIT revenues being recovered in the third rate bracket

Note: The analysis assumes no behavioural change and linearity from the employee SSC rate reductions. Total PIT and SSC in the microdata differ from figures reported by Ministry of Finance. Methodological information on the microdata is available in the annex.

3.3. Find alternative way of financing the welfare system

132. **Lowering the employee SSC rate will have an impact on the financing of the social security system.** Slovenia's welfare system relies mainly on funding through SSCs (Figure 3.8). Despite of the high SSC rates, the pension and health funds face important funding constraints which are expected to worsen given the rapidly ageing population and the increase in costs associated with pensions and long-term care. Therefore to compensate for a cut in employee SSC rate and to ensure sufficient funding for the social security system, different reform options could be envisaged, including financing the welfare system more strongly through general taxation or shift some employee SSC towards employer SSC. These different options will be evaluated below.

Figure 3.8. Slovenia's welfare system relies mainly on funding through SSCs

Note: "Other" includes compulsory prepayment and other domestic revenues.

Source: (OECD, 2017_[12]).

3.3.1. Financing the welfare system partly through general taxation

133. **Strong arguments exist to finance social benefits through general taxation (e.g. the PIT or other taxes levied on capital income, immovable property or consumption) if there is no strong link between contributions made and benefits received** (Brys et al., 2016_[24]). This is the case for child benefits or family related tax provisions, and might also apply to unemployment insurance, in particular if the level of unemployment benefits is not strongly linked to contributions made. If a shift towards general taxation is accompanied by a reduction in employee SSCs, it can help reducing labour costs. Levying social contributions through a progressive PIT can also be a possibility, in particular if the burden could be shifted to workers and income levels with lower labour income tax elasticities. In addition the PIT can have a broader tax base as it can be levied on capital income, such as the case of France (see Chapter 6).

134. **In a changing world of work, financing social benefits partly through general taxation would not only increase labour market participation but could possibly also ensure that welfare support remains available for a large number of people.** Structural changes in the economy as a result of digitalisation, automation and other trends are resulting in an increasing numbers workers which pay lower levels of SSCs (self-employed, temporary workers and workers with irregular working hours) (OECD, 2017_[25]). This trend presents new challenges not only for tax administrations but also for welfare systems financed primarily by SSCs.

135. **Across the OECD, unemployment insurance and maternity benefits are financed through general taxation although differences across countries exist.** In Slovenia, the SSCs for unemployment benefits and maternity leave are paid to the general government budget (no special funds are in place) and the state budget pays for the corresponding spending. Many countries (including Slovenia) finance unemployment insurance with SSCs, but in many cases also with general taxation (which can amount to as much as two-thirds of the program's expenditures) (Office of Research, Evaluation and Statistics, 2016_[26]). Maternity benefits are often funded mainly through general

taxation (European Commission, 2017_[27]). In some countries, such as Poland, family benefits are paid through general taxation (World Bank, 2007_[23]).

136. **As a measure to cut employee SSCs in Slovenia, the SSCs for unemployment and maternity leave could be abolished. The corresponding benefits could be financed through general taxation, as is already the case.** Such a reform would require an increase in general taxation to compensate for the cut in SSCs. However as the respective rates are low (0.14% for unemployment insurance and 0.10% for maternity leave) this would not entail a large reduction in the overall employee SSC rate (from 22.10% to 21.86%). The impact on both the net personal average wage and the average tax wedge would be minimal.
137. **Slovenia might consider other reforms to reduce employee SSCs beyond a cut in the contributions for unemployment and maternity leave.** Different options exist, as will be discussed further in this chapter, including financing the health system partly through general taxation. In addition, the pension system could increasingly be funded from general taxation, as is partly already the case.

3.3.2. Shifting employee SSCs to employer SSCs is not the way forward

138. **While shifting SSCs partly from the employee to the employer would stimulate labour market participation, it might reduce job creation in the private sector.** The current SSC mix in Slovenia relies more heavily on employee than on employer SSCs, in contrast to the SSC mix in most other OECD countries (Figure 3.1). This then raises the question of whether the tax mix could be partly shifted away from employee towards increased employer SSCs. In the short run with fixed wages, a cut in employee SSCs financed by an increase in employer SSCs would increase household disposable income and increase the total labour cost for the employers. In that sense, the shift would be similar to an increase in gross wages across all sectors and for all workers irrespective of workers' productivity.
139. **By increasing labour costs, an increase in employer SSCs might make it too expensive for employers to hire certain types of workers** and in particular those workers who already face challenges in finding a good-quality job, such as low-skilled and older workers. As increased labour market participation is the most straightforward strategy for Slovenia to put the funding of its welfare system on a secure footing for the future, financing a cut in employee SSCs by higher employer SSCs might not be a first-best strategy.
140. **Slovenia implements a minimum SSC base for workers earning less than a minimum income threshold.** For gross earnings below the minimum income threshold, SSCs are calculated on the basis of the minimum SSC base and not on actual gross wage earnings. Employees are liable to pay employee SSCs on their actual gross earnings. However, the employers are liable to pay, in addition to the employer SSCs levied on workers' gross earnings, the employee and employer SSC rate on the gross wage earnings below the minimum income threshold. A minimum SSC base applies also to self-employed workers.
141. **The minimum SSC base for regular employees is legislated to increase significantly over the following years.** The minimum SSC base has been increasing from 52% of the AW to 54% of the AW in 2018. It will increase further to 56% of the AW in 2019, 58% in 2020 and 60% in 2021. Self-employed workers face already a 60%

of the AW minimum SSC base in 2018. The different bases for regular employees and self-employed workers are therefore planned to converge over time.

142. **The minimum SSC base significantly increases the effective employer SSC rate for low-income workers.** The minimum SSC base has the effect of increasing the SSC rate which employers have to pay on low incomes as follows:

employer SSC rate = statutory employer SSC rate + (employer SSC rate + employee SSC rate) * [Max (minimum SSC base – employee gross wage earnings, 0) / employee gross wage earnings]

143. **The increase in the effective employer SSC rate is decreasing in income, thereby leading to a perverse effect that the tax system makes it more expensive (in terms of SSCs that need to be paid) to hire low-income than high-income workers.** Table 3.5 present results for the effective employer SSC rate for different levels of gross earnings. The results show that the effective employer SSCs rate exceeds the statutory rate of 16.1% in 2018 significantly, in particular for very low incomes. In fact, the increase in the employer SSC rate is increasing in the difference between the minimum SSC base and actual gross earnings. The lower are gross earnings, the higher is the effective employer SSC rate. No extra employer SSCs have to be paid for workers earning more than the minimum SSCs threshold.

144. **The minimum SSC base offers another argument not to shift from employee to employer SSCs.** As the minimum SSC base increases the effective employer SSC rate, a further increase in the employer SSC rate might significantly distort the labour market and in particular the employment opportunities for low-income workers. Following practices in other countries (Box 3.1), Slovenia could abolish the minimum SSC base, or, if not possible in the short run, lower it to an income level that corresponds more closely to the minimum wage.

Table 3.5. An extra employer SSC has to be paid up to an income threshold

| With a minimum SSC base of 60% of the AW | | | | | |
|--|-------|-------|-------|-------|--------------|
| Employee wage earnings (% of the AW) | 40% | 45% | 50% | 55% | 60% and more |
| Statutory employer SSC rate (%) | 16.1% | 16.1% | 16.1% | 16.1% | 16.1% |
| Additional employer SSC rate (%) | 7.6% | 5.7% | 3.8% | 1.9% | - |
| Effective employer SSC rate (%) | 23.7% | 21.8% | 19.9% | 18% | 16.1% |

Box 3.1. SSCs thresholds and rates: approaches followed by OECD countries

In most OECD countries, employee social security contributions are payable by all taxpayers on their first unit of earnings.

Minimum thresholds

Some countries implement minimum income thresholds below which social security contributions are not payable. This is the case with all forms of employee social security contributions in seven countries – Austria, Belgium, Iceland, Ireland, Norway, Sweden and the UK – as well as some (but not all) employee SSCs in Canada (pension and health contributions), Luxembourg (dependency insurance) and the Slovak Republic (health insurance).

While some countries exempt low incomes from SSCs, others implement minimum SSC liabilities. In the Slovak Republic, Spain and Turkey, full-time workers are deemed to earn a minimum amount of income subject to SSC. This minimum SSC tax base tends to correspond to the legal minimum wage.

Ceilings

SSC ceilings are more common than minimum income thresholds. Total employee SSCs are capped at a maximum level when an income ceiling is exceeded in 16 OECD countries – Austria, Canada, Chile, the Czech Republic, Germany, Greece, Israel, Italy, Latvia, Luxembourg, Mexico, the Netherlands, the Slovak Republic, Spain, Sweden and Turkey.

In 2017, gross earning ceilings in countries where total SSCs were capped ranged from 0.69 times the average wage in the Netherlands to 6.49 times the average wage in the Slovak Republic.

In most of the countries where total SSCs are capped, the gross earnings threshold at which the maximum SSC contribution is reached is below the threshold at which the top statutory PIT rate begins to apply, which implies that SSC rates do not increase the marginal personal tax rate (encompassing PIT and employee SSC) beyond the top statutory PIT rate for taxpayers facing this top rate. The exceptions are the Czech Republic, Italy, Latvia, the Slovak Republic and Turkey, where taxpayers continue to pay SSC after their income has exceeded the threshold at which the top PIT rate applies.

Rates

Social security contributions are usually levied at a flat rate. The flat rates result in a constant average burden of employee SSCs for most countries between 33% and 167% of average wage earnings. Some examples of a constant proportional burden for employee SSCs for over the eight model family types, are (in decreasing order of rates) Slovenia (22.1%), Hungary (18.5%), Poland (17.8%), Greece (15.8%), Turkey (15.0%), the Czech Republic and Portugal (11.0%), Latvia (10.5%), Norway (8.2%), the United States (7.7%), Chile (7.0%), Switzerland (6.2%) and Estonia (1.6%).

3.4. Reform the SSCs paid by self-employed

145. **Self-employed individuals in Slovenia pay SSCs within minimum and maximum income bands.** SSCs for self-employed workers, irrespective of whether they are taxed under the regular or the “flat-rate” regime, are calculated on 75% of the profit earned in the previous fiscal year. There is also a minimum SSC base, which is as of January 2018, equal to 60% of the AW. Hence, self-employed workers who earn a profit (reduced by of 25%) lower than 60% of the AW, pay SSCs on this minimum income base irrespective of their actual income. In addition, a maximum contribution base is set at 350 % of the AW. About half of OECD countries apply a SSC ceiling. A few countries have no thresholds, or only apply a minimum one. Very few countries apply a lump-sum charge (Denmark, Japan, and Mexico) (see Box 3.1 and the OECD Tax Database for more information).
146. **The SSC rate for the self-employed in Slovenia is high.** The SSC rate equals the sum of the employee and employer SSCs rates for regular employees. On average in the OECD, the self-employed SSC rates are usually higher than the employee SSC rates but lower than the sum of the employee and the employer SSC rates (Table 3.6). Slovenia could therefore consider lowering the SSCs paid by the self-employed similar to the recommended cut in employee SSCs for regular employees.

Table 3.6. Self-employed in Slovenia pay high SSCs

| | Self-employed SSC | SSCs in % | | |
|---------------------|-------------------|-------------------------------|--------------|--------------|
| | | Sum employee and employer SSC | Employee SSC | Employer SSC |
| Austria | 26.15 | 36.6 | 15.12 | 21.48 |
| Hungary | 8.50-10-22 | 40.68 | 18.5 | 22.18 |
| Poland | 30 | 34.14 | 13.71 | 20.43 |
| The Slovak Republic | 47.2 | 48.6 | 13.4 | 35.2 |
| Slovenia | 38.2 | 38.2 | 22.1 | 16.1 |

Note: Some countries have multiple SSCs schedules like Hungary.

Source: OECD Taxing Wages.

147. **Having a separate SSC regime for the self-employed might allow countries to lower the tax burden for the self-employed in order to stimulate entrepreneurship.** Such an approach may stimulate job creation, in particular in countries where SSCs are high such as in Slovenia. However, such a differentiated social security system typically also results in differences in benefit entitlement, which reduces the equity of the tax and benefit system.
148. **In dual income tax (DIT) systems which tax labour and capital income differently for tax and SSC purposes, a separate SSC regime for the self-employed could reflect that the income of the self-employed consists partly of remuneration for work and partly of a return for the capital invested.** Capital income is taxed at lower rates than labour income and SSCs are levied on labour income only under a DIT system. The differential SSC regime in Slovenia for employees and self-employed and, in particular, the 25% exemption of profits for the self-employed, could then be seen as the introduction of a, albeit unsophisticated, mechanism to introduce a differential tax treatment for capital and labour income for the self-employed.

149. **Running different SSC regimes also entails costs for tax administrations and it complicates compliance for workers**, in particular for individuals who are both regular employees and self-employed. It also makes shifts from employment into self-employment (and vice-versa) burdensome and may even involve a loss in benefit entitlement. It may also stimulate tax avoidance and evasion when employees become self-employed just for tax purposes or when they are obliged by their employer to work under a self-employed status (so called bogus self-employment).
150. **In a changing world of work where employment is increasingly becoming flexible, in particular because of digitalisation, tax systems should not create a hurdle to work.** Modern labour income tax systems should be adjusted to ensure that workers can benefit from the flexibility of the modern labour market while maintaining the fairness of the system. As a result, there seems a lot of merit of continuing to tax regular employees and the self-employed under the same SSC regime in Slovenia. Moreover, modern auditing techniques and administrative and IT tools might help increasing tax compliance by the self-employed.
151. **The SSC regimes for the self-employed and regular employees in Slovenia are relatively similar in particular in terms of rates.** The main differences between the regimes are: i) the self-employed can reduce their SSC base by 25%, which does not apply to regular employees; ii) the self-employed can benefit from a special flat rate regime (see below); and iii) the self-employed need to pay SSCs within a minimum and maximum income bound. Differences in benefit entitlements also exist.
152. **The SSC regime for regular employees and the self-employed in Slovenia could, possibly gradually over time, converge.** The two SSC regimes are already aligned in terms of rates, and are converging in terms of minimum SSCs threshold by 2021. Further aligning the two SSC regimes would mean implementing a SSC cap for regular employees at 3.5 times the average wage or abolishing the SSC ceiling for the self-employed. The latter would then require abolishing the maximum pension ceiling for the self-employed (or increasing the maximum pension) in order to maintain the link between SSC paid and benefit entitlements. Moreover, such a convergence of the two regimes would not only have implications for SSCs that are paid but also for the benefits that are received. Benefits would have to be determined following the same rules for both types of workers, which currently is not the case. Box 3.2 presents an estimate of the impact of the introduction of such a cap for employees.
153. **The minimum SSC base for workers ensures that self-employed workers pay a minimum amount of SSCs and, hence, are entitled to a minimum amount of benefits.** On average, self-employed workers earn very low income in Slovenia. Close to 70% of the self-employed pay SSCs on the minimum income base at 60 % of the AW (data from Ministry of Finance of Slovenia).
154. **However, a minimum SSC base which is set at a high income level may create cash flow problems and prevent workers from becoming self-employed.** Slovenia has therefore installed a special regime that provides for a reduction in SSCs for the first 2 years after creating a new self-employed business. Nevertheless, Slovenia should consider abolishing the minimum SSC base or reducing it to an income level which corresponds more closely to the minimum wage.

Box 3.2. Estimates of a SSC cap at 3.5 times the average wage for employees

This box estimates the employee and employer SSC revenue loss associated with introducing a SSC ceiling for employees at 350% of the average wage. Using the average wage in 2016 of EUR 19,016, this gives a ceiling of EUR 66,556.

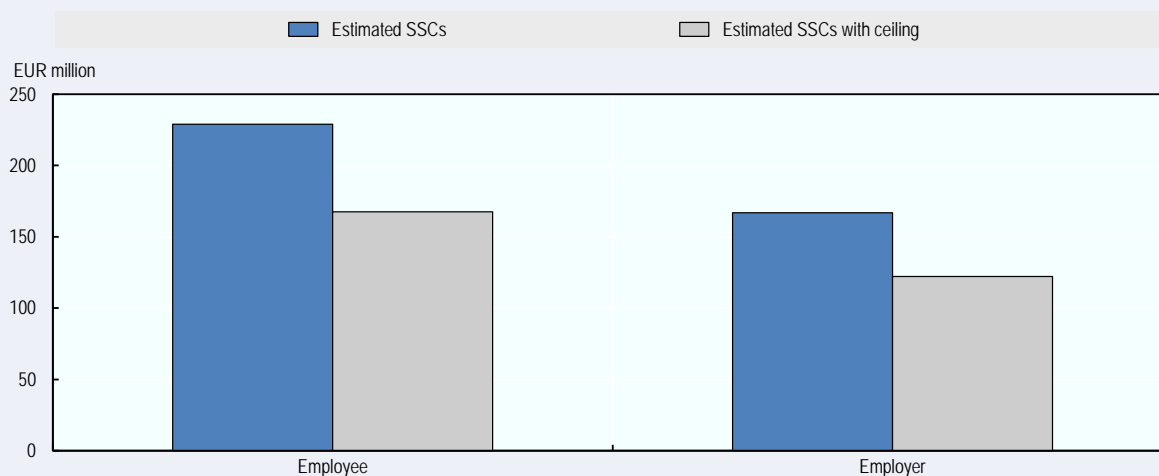

First, employer and employee SSCs are estimated as 22.1% and 16.1% of employment income for each employee in the tax record microdata.

Second, employer and employee SSCs are re-estimated but with a ceiling introduced where SSC payments are capped at 22.1% and 16.1% of EUR 66,556 for employees and employers respectively. In other words, all employees earning above this threshold pay employee SSCs of exactly EUR 14,709 and all employers pay exactly EUR 10,716.

The estimated SSC loss is given by the difference in SSC payments between the two sets of estimates. According to the analysis, the SSC loss associated with introducing a cap at 350% of the average wage for employee is EUR 61 million for employee SSC, and EUR 45 million for employer SSCs, so EUR 106 million in total (Figure 3.9).

Figure 3.9. Introducing an employee and employer SSC cap at 350% of the average wage could reduce SSCs significantly

Total employee and employer SSCs above the 350% of average wage ceiling, in EUR million

Note: Only employees are included. The analysis assumes no behavioural change and linearity. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

3.5. Align the SSC treatment across different type of employment contracts

3.5.1. Align SSCs across different types of workers

155. **SSCs rates vary significantly across different types of employment contracts in Slovenia.** Full-time permanent employees, farmers, short-term work, students, and other types of work pay different SSCs (some examples are illustrated in Table 3.7 and Table 3.8) (European Commission, 2017^[27]). While certain differences in tax treatment might be justified, there is significant scope to unify the SSCs across different types of labour contracts in Slovenia.

156. **Different SSCs regimes reduce the tax base which in turn negatively affects the financing of the health and pension funds.** While full convergence might not be desirable (e.g. for pensioners, unemployed, etc.), moving toward a unification of treatments for SSCs (both bases and rates) across different types of labour contracts should be envisaged. This would not only improve transparency and prevent tax-induced distortions across forms of work but would also strengthen the financing of the social welfare system.

Table 3.7. SSCs rates vary significantly depending on the type of employment contract

| | | Full-time permanent employee* | Person performing an activity as an accessory profession | Farmer*** | Service contracts and other contracts of civil law** | Temporary and casual work of pensioner | Short-time work | Personal supplementary work |
|------------------------|-----------------------------|-------------------------------|--|---|--|--|-----------------|-----------------------------|
| | Base | Wage or wage compensation | Specific cases of insurance | Basis for inclusion in compulsory insurance | | Payment | | |
| Pension & disability | Employee | 15.5 | | 15.5 | | | | |
| | Employer | 8.85 | | | | 8.85 | | |
| | Specific cases of insurance | | 33,01 EUR/month | | | 8.85 | | |
| Health | Employee | 6.36 | 25,78 EUR/month | 6.36 | 6.36 | 6.36 | | Voucher system |
| | Employer | 6.56 | | | | | | |
| | Injury at work | 0.53 | 8,59 EUR/month | 0.53 | 0.53 | EUR 4,86 | EUR 4,86 | |
| Unemployment insurance | Employee | 0.14 | | | | | | |
| | Employer | 0.06 | | | | | | |
| Maternity leave | Employee | 0.10 | | 0.10 | | | | |
| | Employer | 0.10 | | 0.10 | | | | |

Note: *Are taxed at similar SSCs rates: part-time permanent employment contract, full-time permanent employee (posted worker or posted civil servant), self-employed. **The same rules apply for contracts for copyrighted work and other contracts of civil law. ***For farmers who attain the 'income census' (60% of the average monthly salary), pension and disability insurance is mandatory. They pay the employee SSC for pensions and disability (15.5%) and the employer SSC for pension and disability are paid from the state budget (8.85%). The SSC for health is paid also by the employee (rate 6.36 %) and the HIIS pays the employer SSC (6.56%). However they are not insured against unemployment. Their insurance base is similar to the base for self-employed workers. Farmers below the income census might opt for voluntary pension and disability insurance. In this case, the contribution base is 60% of the AW (54% of the AW in 2015; 56% of AW in 2016; 58% of the AW in 2017).

Source: Ministry of Finance of Slovenia.

Table 3.8. SSCs bases vary for health insurance

| | Contribution base | Minimum |
|---|---------------------------|---------|
| Regular employee | Gross wage | yes |
| Self-employed | Profit in the last year | yes |
| Farmers | Profit in the last year | yes |
| Farmers below the income census (i.e. income of at least 60% of the AW) | 60% of average wage | |
| Farmers with no pension insurance* | Cadastral income | |
| Self-payers; daily workers through vouchers | Defined in absolute terms | |

Note: *For farmers who are not included in the pension and disability insurance are obliged to be insured in the health insurance if the income per member of a farm household is at least 25% of the minimum wage. The contribution base is then cadastral income and the SSC rate is 18.78 %.

Source: (European Commission, 2017^[27]); Ministry of Finance of Slovenia.

3.5.2. Maintain or slightly increase the health SSC rate on pension income

157. **In Slovenia, the pension fund pays health SSCs for pensioners at a rate of 5.96% which is slightly lower than the rate of 6.36% which employees pay.** The health SSCs do not reduce the pension which the pensioner receives, so in fact it is a cost paid and borne by the pension fund. The general rationale for imposing SSCs on earned income but not on pension income is that contributions buy an entitlement to future benefits and that pensioners do not have to pay the same level of SSCs as they “saved” in part for their benefit entitlements when they were still active in the labour market (even though in practice, Slovenia operates a pay-as-you-go pension system); levying pension and disability SSCs on the actual pension which pensioners receive would imply double taxation.
158. **The arguments against levying health SSCs on pensions are weak.** In contrast to pension SSCs which entitle workers to a pension in the future, health SSCs entitle workers to health insurance in the year when the contributions are made. Pensioners could therefore be asked to contribute for their health insurance even though they are no longer working but receive a pension instead. Indeed, the policy rationale against health SSCs for pensioners indicates that health SSCs which are paid when taxpayers were active in the labour market not only paid for health insurance in that particular period but consists also of a component which builds up health insurance entitlements for when retired. Such an approach would result in very high health SSCs levied on labour income; it seems also unfair as taxpayers who live longer would benefit more. As a result, Slovenia should maintain its current regime of health SSCs levied on pensions and, in fact, could consider further strengthening it.
159. **Health SSCs paid by the pension fund could be increased in order to match more closely the health care spending on pensioners.** Such a measure would shift the financial burden of health care spending from the HIIS to the pension fund and would help strengthening the financing of the health fund. Arguments exist to levy health SSCs on pensions directly; i.e. health SSCs would not only be a cost for the pension fund, as currently is the case in Slovenia, but would actually reduce the pension received. However, this would lower the pensions received, which are already low for most pensioners. The impact of health SSCs on low income pensioners might have to be compensated through, for instance, PIT relief.

3.6. Increase the financial resources for health care

3.6.1. The Health Insurance Institute of Slovenia carries out a wide range of tasks

160. The health system in Slovenia operates through the Health Insurance Institute of Slovenia (HIIS). It is complemented by three private insurance companies, which provide voluntary insurance to cover the co-payments. Plans exist to integrate these insurances in the HIIS. In 2015, 72% of the health financing came from public funding (Figure 3.10). This is lower than in many OECD countries and below the EU average (79%). Complementary health insurance is rising. About 87% of the population has now a voluntary health insurance (OECD and European Commission, 2017^[29]), which is among the highest in OECD countries, while out-of-pocket health expenditure by households remains relatively low.

Figure 3.10. The share of public health financing is relatively low in Slovenia

Source: OECD Health Database.

161. **The HIIS provides universal health coverage and has a wide range of tasks:**

- Health services (primary health care, dentistry, specialist out-patient services, hospital and tertiary level services, pharmaceuticals etc.);
- Health resort treatment, rehabilitation treatment, transport by ambulance and other vehicles, medicaments, medical devices;
- Sick pay during temporary absence from work exceeding 30 days;
- The reimbursement of travel expenses tied to obtaining health services.

162. **Sick leave benefits amount to 11% of the HIIS expenditures in 2017** (European Commission, 2016^[30]). Slovenia is one of the two countries (with Bulgaria) where sickness benefits can be provided for an unlimited duration. In other EU countries, the maximum legal duration of sickness benefits for work absence ranges from 22 weeks to 3 years.

163. **Since 2008 the HIIS has performed activities going beyond the pure provision of health care.** The HIIS was also in charge of paying for certain non-service delivery items such as health professional training and specialization, medical research,

and postgraduate education. These activities have been recently transferred to the State budget.

164. **Nevertheless, additional opportunities for the HIIS to focus on its core activities exist.** For example, there is room to rationalise the hospital network to raise efficiency. Indeed, Slovenia has still many small regional hospitals, and the bed occupancy rates are below the EU average, suggesting overcapacities. Opportunities also exist to improve the implementation of core activities, such as improving care coordination, substituting day cases for inpatient care, and reducing the reliance on (expensive) specialists (OECD and European Commission, 2017_[29]). An independent health technology assessment would help a better allocation of resources and improve the recently implemented public procurement system. Other sources for improved efficiency include improving the relationships between supervisory institutions, or reinforcing clarity among their responsibilities (OECD and European Commission, 2017_[25]). An in-depth analysis of these issues goes, however, beyond the scope of this report.

3.6.2. *The health system in Slovenia is financed primarily through SSCs*

165. **The HIIS is largely funded through SSCs and not through general taxation.** Health systems can be financed through SSCs, general taxation or a combination of both sources of financing. Different approaches bring both advantages and disadvantages; see Table 3.9 for a discussion. Nearly all other health systems in Europe raise significant funding from general taxation (World Health Organisation, 2016_[27]).

Table 3.9. Different ways of financing health system presents strengths and weaknesses

| | Pros | Cons |
|------------------|--|---|
| General taxation | <ul style="list-style-type: none"> Pool risks for whole population Potential for administrative efficiency and cost control Redistributes between high and low risk and high- and low- income groups in the covered population | <ul style="list-style-type: none"> Risk of unstable funding and often underfunding due to competing public expenditure Inefficient due to lack of incentives and effective public supervision |
| Health SSCs | <ul style="list-style-type: none"> Generate stable revenues Often strong support from population Provides access to a broad package of services Involvement of social partners Redistributes between high and low risk and high- and low- income groups in the covered population | <ul style="list-style-type: none"> Poor are excluded unless subsidized Payroll contributions can reduce competitiveness and lead to higher unemployment Complex to manage governance and accountability can be problematic Can lead to cost escalation unless effective contracting mechanisms are in place |

Source: ILO <http://www.social-protection.org/gimi/gess/ShowTheme.do?tid=3108>.

3.6.3. *The Health Insurance Institute needs more financial resources*

166. **Despite the high health SSCs, the HIIS faces challenges to finance its tasks.** The HIIS is not allowed to engage in deficit spending. Therefore it must either reduce prices, shift costs onto the complementary health insurances, or delay payments to health providers (World Health Organisation, 2016_[31]). This has resulted in losses for some public hospitals. Reforms have been implemented to raise more revenues for the HIIS and reduce expenses, including higher contributions paid by the self-employed, restrictions to the entitlements to free services, increased co-insurance rates, reduced prices of drugs and health services, etc. (World Health Organisation, 2016_[31]). However,

the funding challenges remain and will only increase as a result of the ageing of the population.

167. **Several options exist to provide the HIIS with more (diversified) financial resources.** Those options are described below. However an overall independent assessment of the efficiency and functioning of the HIIS seems warranted and would need to be conducted prior to any reform aimed at raising more revenues. This would help identifying the HIIS funding gaps, it would increase accountability of both the government and the HIIS (evaluation of public spending, better management of public funds, etc.) and it would contribute to improved quality of the services delivered.
168. **First, the HIIS could perform a more limited number of core tasks. Several options exist.** The entitlements to sick leave benefits financed by the HIIS could be restricted over time. Instead of being on sick leave for very long periods of time, people would receive a disability benefit or a pension instead. While this not necessarily will reduce overall government expenditure, it will involve a shift in how these benefit entitlements are financed, away from the HIIS which is funded through SSCs towards general taxation. As long-term care insurance in Slovenia is covered by the HIIS, another option would be to assign all long-term care responsibilities to a newly created “long-term care” fund. This new fund could then be financed through general taxation.
169. **Second, the employee health SSC base could be broadened by limiting the differences in contribution rates and bases and by treating different types of incomes for SSC purposes more alike.** These issues have been discussed before. Such a reform would have to take the possible differences in benefit entitlements into account.
170. **Third, the health employee SSC rate could be maintained.** Given the overall cut in employee SSCs which this report calls for, this would then imply that pension employee SSCs would be cut considerably and that pensions would be financed increasingly through general taxation. The level of health contributions could be re-evaluated once the independent review of the Health fund has been undertaken.
171. **Fourth, the health SSCs paid by pensioners could increase.** This option was discussed in more detail in section 3.5.2.
172. **Most importantly, an increase in the number of people who are at work and an increase in the effective retirement age would significantly increase the financial resources for the HIIS.** Increasing labour market participation is crucial for government to finance its health care system over the decades to come.
173. **If these measures would turn out not be sufficient over time to put the financing of the HIIS on a solid footing, government could introduce other measures.** These could include partly financing the HIIS with revenues from general taxation. General taxation could possibly finance the well-defined non-core activities performed by the HIIS such as sick leave benefits. Such a shift can, however, not be without limits in order to safeguard the country’s financial stability. Moreover, a shift towards general taxation would require a strong health budgeting framework and an independent assessment of the efficiency and functioning of the HIIS. Such an assessment would include an objective analysis of the gap in revenues for the HIIS in light of its spending needs over the next decade(s).
174. **Excise duties on alcohol and cigarettes can also contribute to the financing of the HIIS.** However, strong arguments exist against the earmarking of tax revenues to finance the HIIS and this route should not be taken by Slovenia. Excise duties generally

levy relatively small revenues and, when the rates are set too high, can lead to cross-border shopping. In that context, a further increase in excise duties should be introduced gradually and rates should not be set too high (see Chapter 5). Even if revenues from alcohol and tobacco taxation could contribute to the financing of the HIIS, these excise duties should continue to be paid to the general state budget and not be earmarked to finance the HIIS.

175. **The different options for reforms can be complementary and introduced gradually.** The employee SSCs base broadening and the employee health SSC rate increase would be the priorities, followed by the financing of non-core activities through general taxation. In a second stage, if the recent transfer of tasks from the HIIS to the Ministries of Health and Education, combined with the compensation of the HIIS from general taxation for specific tasks, do not raise sufficient revenues, alternative source(s) of financing could be considered.

3.7. Main recommendations

Box 3.3. Recommendations to strengthen the social security system

Objective: Reduce employee SSCs

- Reduce the employee SSC rate across all income levels significantly
- Evaluate how the role of the PIT could be strengthened to ensure that the benefits of the employee SSC reduction are shared more equally and have the largest bang for the buck in terms of increased labour market participation
- Abolish the contributions for maternity leave and unemployment, and continue to finance the corresponding benefits from general tax revenue
- Reduce pension employee SSCs and, possibly, increase employee health SSCs (but such that the overall employee SSCs decrease)
- Increases in employer SSCs should not finance a cut in employee SSCs

Objective: Lower the minimum SSC income base

- Lower the minimum SSC base to prevent excessively high effective employer SSCs being levied in respect of low income workers

Objective: Align the SSCs for regular employees and the self-employed

- Reduce the self-employed SSCs across all income levels (i.e. similar to the cut in employee SSCs)
- Align the employee and self-employed SSC regimes as much as possible
 - Maintain similar SSC rates (i.e. sum of employee and employer SSC rates for employees equal to self-employed SSC rates)
 - Abolish the minimum SSC base for the self-employed, or if not possible in the short run, lower it to a level that corresponds more closely to the minimum wage
 - Evaluate the SSC ceiling at 350% of the AW. Possibly abolish it and increase the maximum pension for self-employed
- Instead of exempting 25% of the profits earned by the self-employed from tax, evaluate whether a more explicit distinction can be made between the return for labour and capital invested in the self-employed business, and tax the different earning streams separately

Objective: Broaden the SSCs base

- Streamline the different SSC treatments across different types of labour contracts (in particular for health SSCs)
- Increase labour market participation of young and older workers in particular as a strategy to strengthen the financing of the welfare system
- Maintain, or slightly increase, the health insurance SSC paid by the pension fund. Possibly levy a health SSC rate paid by pensioners but offset the impact on low pensions through PIT relief

Objective: Evaluate the link between SSCs paid and benefits received

- Increase the link between SSCs paid and benefits received without imposing an excessively high tax burden on labour income

Objective: Increase and diversify the financial resources dedicated to health care

- Conduct an overall independent assessment of the efficiency and functioning of the Health Insurance Institute of Slovenia (HIIS)
- Allow the HIIS to focus on its core tasks
 - Limit the entitlement to sick leave benefits financed by the HIIS over time
 - Possibly transfer the responsibilities of long-term care to a newly created fund
- Over time, and if necessary, increase the share of general taxation in health financing, including the revenues from excise duties on alcohol and tobacco. Prevent earmarking of tax revenues to finance the HIIS

Chapter 4. Strengthening the design of the Personal Income Tax

Significant scope exists to strengthen the role of the PIT in Slovenia. A significant cut in employee SSCs needs to go hand in hand with re-designing the PIT rate schedule in order to obtain the largest bang-for-the buck in terms of increased labour market participation, to share the gains of the employee SSC reduction fairly across the income distribution and to help financing the reform. The personal income tax increases the tax burden on labour income significantly, in particular for higher income earners. The top PIT rate of 50% is very high, in particular in combination with the high employee SSCs. Reducing the top PIT rate would come at a relatively low tax revenue cost. Low incomes face a lower tax burden, mainly as a result of generous basic allowances. However, the reduction of the basic allowance at higher income levels increases marginal tax rates and, therefore, the incentives to increase work efforts. Most taxpayers are concentrated in the lower rate bands. The tax base is relatively narrow as a result of exemptions and special tax provisions. Tax provisions take the form of tax allowances, which is in contrast to best practice in the OECD, where tax credits are more widely used as tax credits provide the same benefit to all taxpayers irrespective of their income and marginal tax rates. Broadening the tax base can in particular be achieved by abolishing the tax exemption for the reimbursement of home-work travel expenses and meals during work. While single taxpayers face a very high tax burden, families with children are taxed a lot less. They can benefit from both child tax allowances and child cash benefits. The design of these provisions is complex and could be reformed. Secondary earners face high marginal tax rates, partly as a result of the decline in child benefits at higher income levels. High tax burdens on labour income reduce the incentives for entrepreneurship. In response, Slovenia has introduced an alternative “flat-rate” tax regime for self-employed entrepreneurs. However, the regime is overly generous and induces entrepreneurs to conceal their income and prevents businesses from growing. Self-employed who do not choose for the generous “flat-rate” regime face a strong tax-induced incentive to incorporate in order to transform highly taxed labour income into low-taxed capital income. The tax burden on labour and capital income could be aligned by lowering the tax burden on labour income and increasing the tax burden on capital income.

4.1. Redesign the PIT rate schedule

176. **The PIT rate schedule is progressive.** It is composed of five tax brackets similarly to the OECD average in 2016, with a top statutory PIT rate of 50% (Table 4.1). Certain types of income are taxed at a flat rate and are discussed in section 6.2.1. As described in Box 1.2, before the 2016 PIT reform Slovenia had four tax brackets. The reform has introduced as of January 2017 an additional tax bracket (34%) and has lowered the second highest tax rate (from 41 % to 39 %).

Table 4.1. Tax schedule

| | Taxable income (EUR) | Tax on lower amount (EUR) | Rate on excess (%) |
|----------|----------------------|---------------------------|--------------------|
| Up to | 8 021.34 | 0 | 16 |
| 8 021.34 | 20 400 | 1 283.41 | 27 |
| 20 400 | 48 000 | 4 625.65 | 34 |
| 48 000 | 70 907.20 | 14 009.65 | 39 |
| Over | 70 907.20 | 22 943.46 | 50 |

4.1.1. The top PIT rate is high

177. **The top statutory PIT rate in Slovenia is 50%, which is amongst the highest top PIT rates in the OECD (Figure 4.1).** The top PIT rate in Slovenia has to be paid on gross earnings above 5 times the average wage, which is a relatively high income level. The top PIT rate kicks in at lower income levels in the Slovak Republic (at 3.5 times the AW), Italy (2.7 times the AW), and the Czech Republic (0.3 times the AW). However, the top PIT rate kicks in at higher income levels in Austria, Germany and France, for instance.

178. **A comparison of top PIT rates and top income tax brackets (i.e. the income level where the top PIT rate hits first) point at major differences across the OECD (Figure 4.2).** Many East European countries have a low top PIT rate which hits at low income levels while Nordic countries have a high top PIT rate which has to be paid at low income levels. France and Portugal (and to a lesser extent Austria) have both a high PIT rate and a high top income tax bracket. In this sense, Slovenia is more similar to Italy and Austria than it is to other SEE countries.

Figure 4.1. The top statutory PIT rate in Slovenia is among the highest in OECD countries

Source: OECD Tax Database.

Figure 4.2. The top PIT rate in Slovenia is levied on high incomes only

Source: OECD Tax Database.

179. **The combination of a high top PIT rate and high employee SSCs results in high marginal effective tax rates for high income earners.** The top “all-in” marginal tax rate, which takes the top PIT rate and employee SSCs into account, in Slovenia is 61.1% which is the highest rate in the OECD (Figure 4.3). On each additional euro earned, a taxpayer in the top PIT income tax bracket pays 61 cents in tax and keeps 39 cents in net pay only. This could induce taxpayers to work less or engage in tax avoidance behaviour. High effective top PIT rates may also make it difficult for firms to attract highly skilled foreign workers and retain Slovenian workers who may prefer to work abroad where working pays more.

Figure 4.3. The top marginal tax rate which employees have to pay is very high

Top marginal “all-in” tax rate, taking into account PIT and employee SSCs, 2017

Note: The top “all-in” tax rate is calculated as the additional personal income tax, plus employee social security contribution, resulting from a unit increase in gross wage earnings at the earnings threshold where the top statutory personal income tax rate first applies. It takes account of the effects of tax allowances, tax credits, etc.

Source: OECD Tax Database.

180. **The top PIT rate results in very high personal average and marginal tax rates for high-income taxpayers.** Figure 4.4 presents net personal average and marginal tax rates at different income levels. The analysis shows strong increases in effective tax rates starting from the income level where the top PIT rate hits first. The net personal marginal tax rate increases with 8.5 percentage points from 52.5% to 61% at the top income tax bracket.

Figure 4.4. Abolishing the current top PIT rate would significantly reduce personal average and marginal tax rates

Note: The net personal average tax rate is defined as the sum of PIT and employee SSCs, minus cash benefits as a percentage of gross wage earnings. The net personal marginal tax rate shows the part of an increase of gross wage earnings that is paid in PIT and employee SSCs net of cash benefits.

Source: OECD Taxing Wages.

181. **The current revenues raised from the top PIT rate are relatively minor.** In 2016, the top PIT rate was paid by 3,581 taxpayers only (Ministry of Finance of Slovenia tax record microdata). This reflects the condensed wage distribution in Slovenia, and possibly also the fact that taxpayers have organised their economic activities such that they can avoid paying the top PIT rate (e.g. through incorporation). The tax revenue cost of lowering the top PIT rate would be relatively modest, as presented in Box 4.1, while it would reduce significantly the tax burden on labour income and, therefore, strengthen the functioning of the labour market.

182. **A significant cut in the top PIT rate in Slovenia would be necessary in order to align the country's top "all-in" marginal tax rate with the "all-in" rates in neighbouring countries.** Slovenia's "all-in" marginal tax rate is the highest of the OECD (Figure 4.3) at 61.1%. For a given level of employee SSCs (either the current 22.1% rate or a reduced rate), Table 4.2 presents the top PIT rate which Slovenia would need to levy in order to reach a top "all-in" marginal tax rate equal to the rate levied in the country of comparison. In all the scenarios which are presented, Slovenia would have to lower its top PIT rate significantly. For example, with a 5 pp cut in employee SSCs to 17.1%, Slovenia's top PIT rate would need to be reduced to 43.1% in order to levy the top marginal "all-in" tax rate of 52.8% in Italy. For smaller cuts in employee SSCs, Slovenia's top PIT rate would have to be reduced even more. However, the comparison

of top PIT rates should also take into account the income level where it kicks in; that complexity is not taken into account in Table 4.2.

Table 4.2. Slovenia's top PIT rate should decrease significantly in order to align the country's top "all-in" marginal tax rate with the rates in neighbouring countries

Top PIT rate in Slovenia for different levels of employee SSCs

| | Employee SSC (%) [*] | Top statutory PIT rate (%) | Top marginal all-in tax rate (%) | New top PIT rate in Slovenia with a cut in employee SSC of... | | | | | |
|-----------------|-------------------------------|----------------------------|----------------------------------|---|---------------|---------------|---------------|---------------|---------------|
| | | | | 5 pp to 17.1% | 4 pp to 18.1% | 3 pp to 19.1% | 2 pp to 20.1% | 1 pp to 21.1% | 0 pp to 22.1% |
| Italy | 9.49 | 47.2 | 52.8 | 43.1% | 42.4% | 41.7% | 40.9% | 40.2% | 39.4% |
| Germany | 20.78 | 47.5 | 47.5 | 36.7% | 35.9% | 35.1% | 34.3% | 33.5% | 32.6% |
| Austria | 17.98 | 48 | 48 | 37.3% | 36.5% | 35.7% | 34.9% | 34.1% | 33.2% |
| Poland | 17.83 | 32 | 39.9 | 27.5% | 26.6% | 25.7% | 24.8% | 23.8% | 22.8% |
| Slovak Republic | 13.40 | 25 | 35.1 | 21.7% | 20.8% | 19.8% | 18.8% | 17.7% | 16.7% |
| Czech Republic | 11 | 15 | 31.3 | 17.1% | 16.1% | 15.1% | 14.0% | 12.9% | 11.8% |
| Hungary | 18.50 | 15 | 33.5 | 19.8% | 18.8% | 17.8% | 16.8% | 15.7% | 14.6% |

Box 4.1. Estimation of the loss in revenues with a reduced top PIT rate

In 2016, there are approximately 3,000 employees with taxable income above EUR 70,907.20, the threshold for the top 50% PIT rate. This cohort has EUR 122 million of taxable income above the threshold which is subject to the top rate. Therefore, assuming no behavioural change and linearity, a reduction in the top PIT rate to 45% is associated with a PIT loss of about EUR 6 million (Figure 4.5). The abolition of the top rate, modelled by reducing the rate to the second from top 39% rate, is associated with a loss of EUR 13 million or 0.03% of GDP.

Although such estimates are uncertain, they can indicate the likely extent of the tax loss – in this case, the PIT loss associated with abolishing the top PIT rate is likely to be very small relative to total PIT collected. At the same time, this loss could be compensated for by creating actual and perceived incentives for a range of potentially positive behavioural responses, which could improve economic efficiency. For example, these high income employees may respond by working more or decreasing the extent to which they avoid taxes. Furthermore, it may reduce emigration of high skilled employees and provide a signal to foreign companies to relocate their activities to Slovenia.

Figure 4.5. The PIT loss associated with abolishing the top PIT rate is likely to be very small relative to total PIT collected

Note: The analysis assumes no behavioural change arising from the PIT rate reduction and linearity. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

4.1.2. The bottom PIT rate hits at a relatively high income level

183. **Single taxpayers start paying income tax at 45% of the average wage.** This is above the OECD average and the selected East European countries (Figure 4.6). The income level where taxpayers effectively start paying PIT depends on the level of tax allowances and/ or the width of the zero rate bracket (if present) in the PIT rate schedule. As families with children and married couples may benefit from additional tax

allowances or cash benefits, those families will have to start paying PIT at income levels typically higher than single taxpayers.

184. **Employee SSCs increase the income level where taxpayers effectively start paying PIT.** In almost all OECD countries, employee SSCs are deductible from taxable personal income. The higher the employee SSCs, the higher the income level where the PIT hits first. A reduction in employee SSCs in Slovenia would also imply that households would have to start paying PIT at lower income levels.

Figure 4.6. The bottom PIT rate hits at a relatively high income level

Source: OECD Taxing Wages.

4.1.3. The PIT increases the labour tax burden significantly

185. **Single employees without children face high tax burdens on their labour income.** The combination of high employee SSCs and PIT rates result in high net personal income tax rates across the income distribution (Figure 4.7). Average tax wedges, which include also the impact of employer SSCs, are even higher. At low income levels, the steep increases in the net personal average tax rate were driven by the specific design of the general tax allowance before its most recent reform. In addition to the general tax allowance of EUR 3 302.70, an additional general allowance of EUR 3 217.12 was available to lower income taxpayers (with taxable income below EUR 10 866.37); taxpayers with taxable income between EUR 10 866.37 and EUR 12 570.89 could benefit from an additional tax allowance of EUR 1 115.94. Once the taxpayer earned income above the particular income thresholds, the tax allowances were lost, which resulted in very high marginal effective tax rates.

186. **The basic allowance system was reformed in 2018** (see Table 4.8); the reform will reduce the two peaks observed in the net personal marginal tax rate, as the allowances will be gradually reduced when income rises. However, the tapering out will result in somewhat higher marginal tax rates over the income range where the additional tax allowances are tapered out compared to the results presented in Figure 4.8. Slovenia should evaluate the impact of the new basic allowance on work incentives and should

evaluate whether the additional basic allowance, instead of tapering it out with income, could be integrated within the standard basic allowance of EUR 3 302.70. In order to prevent that higher incomes would gain, the first rate bracket of 16% could be increased. Moreover, the basic tax allowance could be turned into a basic tax credit to further limit the regressive effects.

187. **Both low and high income taxpayers face high tax burdens.** The net personal average tax rate for taxpayers earning 250% of the average wage amounts to 41% of gross wage earnings, which is significantly above the tax burden on average in the OECD (at 34%). These results are driven by the high employee SSCs and the progressive PIT rate schedule (as pointed out in Chapter 2). High employee SSCs result in high tax burdens on low incomes. For instance, lower-income taxpayers earning 50% of the AW pay 23% of their gross wage earnings in tax, which is above the average rate of 17% on average in the OECD.

Figure 4.7. The relatively high PIT rates increase the labour tax burden significantly

Source: OECD Taxing Wages 2018.

Figure 4.8. The new basic allowance system will reduce the peaks observed in the net personal marginal tax rate at low income levels

Marginal tax wedge decomposition by level of gross earnings expressed as a % of the AW, single taxpayer without children

Source: OECD Taxing Wages 2018.

188. **Actual tax return data confirm the high average tax burdens paid by employees** (Box 4.2). In contrast, the effective average tax rates paid by full pensioners (i.e. pensioners who, besides a pension, do not have another source of wage or business income) or the self-employed are significantly lower.

Box 4.2. The labour tax burden in Slovenia is high

Figure 4.9 shows PIT and SSCs as a share of total labour costs by percentile in 2016 for employees (Panel A), full pensioners (Panel B) and self-employed (Panel C).

For employees, PIT as a percentage of labour costs is extremely low at the bottom of the distribution and increases slowly but progressively for higher incomes. For the first 10 percentiles, it is at or below 0.3% and for the first 30 percentiles it remains below 5.0%. It does not exceed 10% until the 78th percentile. In absolute terms, employee SSCs are always higher than the employer SSCs over the income distribution (except for the first percentile) and the difference increases progressively for higher income levels.

The average tax wedge increases slowly but progressively for higher levels of earnings - from a low of 32% to a high of 48%. For example, at the bottom 10th percentile, where average total labour costs are EUR 9,102 (average gross incomes are EUR 7,834) the average tax wedge is 32%. At the median, where average labour costs are EUR 18,392, the tax wedge is 38%. In the 90th percentile, the tax wedge is 43%.

Figure 4.9. The labour tax burden is high in Slovenia

PIT and SSCs as % of total labour cost, personal average tax rate as % of gross income, 2016, by labour cost percentile

4.1.4. Taxpayers are concentrated in the lower rate bands

189. **Employees pay a large share of the PIT.** Most taxpayers are employees (53%) or pensioners (42%) and a small proportion are self-employed (5%) (Table 4.3). The proportion of income held by employees is 70% while the share of the PIT paid is 89%. For pensioners, the proportion of income held is 26% while the share of the PIT paid is 7%. For self-employed, both shares are 4%. This is reflected in the effective PIT rates for employees (12%), pensioners (2%) and self-employed (9%).
190. **Pensioners and self-employed are concentrated in the first rate band.** In 2016, 87% of pensioners and 84% of self-employed are in the 16% tax bracket. Their base for taxable income is narrowed by a combination of high employee SSCs and substantial allowances (and to a lesser degree by tax credits in the case of pensioners) resulting in very small effective PIT rates and associated PIT. Therefore, most of the very small amounts of overall PIT paid by pensioners and the self-employed are paid by the remaining narrow base of taxpayers. For example, half of all PIT (48%) paid by pensioners is paid by 1.4% of taxpayers (7,973 individuals) in the top two brackets. Similarly for the self-employed, 60% of all PIT paid by the self-employed is paid by 4.6% (3,146 individuals), again in the top two brackets.
191. **The vast majority of employees are in the first two bands.** 50% of employees are in the 16% rate band, and 40% in the 27% rate band. These first two bands account for 55% of the PIT, and 70% of the PIT and SSCs combined. The 3,021 employees (less than 1% of all employees) in the top band earn 3.3% of all income and pay 4% of total tax and SSCs (as a share of gross income).
192. **Disposable income declines only modestly across age in Slovenia.** Even though most taxpayers who are at work pay the bottom PIT rates only, the combination with high employee SSCs reduces their disposable income significantly. Pensioners, on the other hand, pay only small amounts of SSCs and their pension is on average so low that they pay hardly any PIT. The combination of these factors explains why disposable income remains relatively constant when workers move into retirement. Figure 4.10 shows median gross and disposable income in 2016 by age in Slovenia. There is a significant difference between gross and disposable incomes for the working-age population but the gap virtually disappears for those aged over 65. For example, while median gross incomes declined sharply (by 26%) between the ages of 58 and 60, disposable incomes declined only modestly (by 12%).

Figure 4.10. While gross incomes decline sharply as taxpayer's transition to old-age disposable incomes decline only moderately

Median gross and disposable income in 2016, by age

Note: Disposable income defined as gross income less employee SSCs less PIT as reported on the tax records. Methodological information on the microdata is available in the annex.

| 41% | 2,884 | 137 | 131 | 27 | 94 | 28 | 8 | 6 | 21% | 27% | 31% |
| 50% | 262 | 37 | 36 | 8 | 32 | 13 | 1 | 1 | 37% | 39% | 40% |

Note: The table presents only 4 tax brackets as the fifth tax bracket introduced in 2016 took effect as of 1 January 2017. The effective PIT rate is defined as the amount of PIT divided by gross income. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

4.1.5. The effectiveness of the PIT is enhanced by an employee SSC rate cut

193. **This section extends the previous employee SSC rate cut simulation (presented in Chapter 3, section 3.2) to include PIT rate increases.** The previous employee SSC rate cut analysis showed that a 5.24 percentage point cut could result in a loss of EUR 519 million (cost of employee reduction of EUR 700 million net of a PIT recovery of EUR 181 million). Table 4.4 extends that analysis by showing the potential additional PIT revenues from increasing the PIT rate in brackets one to four given the employee SSC rate cut and not.

194. **According to the analysis, the overall effectiveness of the PIT is enhanced by an employee SSC rate cut.** Employees now have higher taxable income and some employees move up to higher PIT brackets. For example, a two percentage point increase in the PIT rate in the second, third and fourth brackets is estimated to produce EUR 61 million for no change in employee SSC, and EUR 71 million if employee SSCs were reduced to 16.86%. A simulation is also provided showing the impact of PIT rate increases given a significant base broadening - reducing tax allowances for all employees by 15%. The analysis shows that, given a broader tax base, smaller PIT rate increases that are necessary to offset other employee SSCs reductions.

Table 4.4. The effectiveness of the PIT is enhanced by an employee SSC rate cut

Cumulative PIT revenues from selected PIT rate increases, for reductions in employer SSC and allowances

| PIT Rate Bracket Increases of: | 1% | 2% | 3% | 4% | 5% | 6% |
|---|-----------|------------|------------|------------|------------|----|
| Employee SSC Rate of 22.1% | | | | | | |
| First | 41 | 82 | 123 | 164 | 205 | |
| Second | 22 | 45 | 67 | 90 | 112 | |
| Third | 7 | 14 | 21 | 28 | 35 | |
| Fourth | 1 | 2 | 4 | 5 | 6 | 7 |
| Total | 72 | 143 | 215 | 287 | 358 | |
| Employee SSC Rate of 16.86% | | | | | | |
| First | 43 | 85 | 128 | 170 | 213 | |
| Second | 26 | 51 | 77 | 103 | 128 | |
| Third | 8 | 17 | 25 | 34 | 42 | |
| Fourth | 1 | 3 | 4 | 6 | 7 | 9 |
| Total | 78 | 156 | 234 | 313 | 391 | |
| Employee SSC Rate of 22.1% and reduced Allowances of 15% | | | | | | |
| First | 43 | 87 | 130 | 174 | 217 | |
| Second | 25 | 49 | 74 | 98 | 123 | |
| Third | 8 | 15 | 23 | 30 | 38 | |
| Fourth | 1 | 3 | 4 | 5 | 6 | 8 |
| Total | 77 | 154 | 231 | 308 | 384 | |

Note: The analysis assumes no behavioural change and linearity from the employee SSC rate reductions. Total PIT and SSC in the microdata differ from figures reported by Ministry of Finance. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

4.2. Unify and broaden the PIT base

4.2.1. The design of the PIT base is complex and rules depend on the type of income earned

195. **The PIT differentiates between six categories of income:** employment income, personal business income, income from agriculture and forestry, rents and royalties, capital income (including rental income), and other income. In order to calculate the personal income tax liability, the tax base of each of the different sources of income are determined separately and afterwards aggregated. According to the microdata for 2016, gross income is about EUR 21.2 billion, of which EUR 19.7 billion or over 90% is employment income (Table 4.5). Salaries (64.1% of total income) and pensions (20.6%) constitute the largest share of total gross income. Personal business income, income from agriculture, rental income and capital income comprise 2.7%, 0.5%, 1.8% and 1.4% of total income respectively.

Table 4.5. Gross income comprises mainly salaries and pensions incomes

Based on 1.5 million taxpayers, 2016

| | Income (EUR millions) | Income (% of total income) |
|---------------------|--------------------------|-------------------------------|
| Gross income | 21,268 | 100% |
| Employment | 19,740 | 92.8% |
| Salary | 13,631 | 64.1% |
| Pension | 4,377 | 20.6% |
| Other employment | 1,733 | 8.1% |
| Business income | 579 | 2.7% |
| Standard regime | 415 | 1.9% |
| Flat-rate regime | 164 | 0.8% |
| Agriculture | 103 | 0.5% |
| Capital | 677 | 3.2% |
| Other income | 168 | 0.8% |

Note: Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

The employment income tax base is narrow

196. **For a regular employee the tax base is income from employment reduced by mandatory employee social security contributions.** Employment income consists of: income from an employment relationship including holiday payments, income from other contractual relationships, and fringe benefits such as the use of a personal vehicle for private purposes, accommodation, a loan free of interest or with an interest rate lower than the market interest rate, etc.

197. **However, special tax rules apply that narrow the tax base considerably.** As from January 2017 onwards, annual bonuses are exempt from PIT, but not from SSCs, up to an amount equal to 70% (up to 100% from 2018 onwards) of the average salary in Slovenia. Some benefits in kind are also exempt from PIT, including subsidized meals during work, catering, mobile phones and computer equipment, and additional education and training expenses related to the business of the employer, etc.¹⁵ Other special tax rules include the deduction from the taxable income of premiums of voluntary pension and disability insurance up to 24% of the mandatory contributions for pension and disability insurance, with a maximum of EUR 2 390 per year.

198. **In addition, the reimbursement of expenses incurred in relation to work-related travel is not taxed under the PIT** (up to a certain amount). This includes transportation costs to and from work (cheapest public transport from the residency to the workplace, or the cost of the mileage EUR 0.18 per kilometre – see Table 4.6 for the average allowance by employee), expenses for meals (maximum EUR 6.12 for each day with more than 4 working hours – see Table 4.6), and expenses incurred on business travels (from 32 EUR to 64 EUR a day on average). Any amount received

¹⁵ Other exempted benefits in kind include: specific health care doctor visits, vaccination and insurance for work accidents; use of parking places, mobile phones and computer equipment; Christmas gifts to the employees' children younger than 15 years (up to EUR 42); non-cash gifts to employees (up to EUR 15 per month).

above the tax-free threshold is included in the tax base for employment income and subject to PIT and SSCs.

Table 4.6. The transport to work and meal allowances are tax exempt

Yearly average allowance by employee in EUR, 2017

| | Private sector | Public sector | Total |
|-----------------------------|----------------|---------------|-------|
| Transport to work allowance | 967 | 875 | 945 |
| Meal allowance | 970 | 661 | 893 |

Note: This table presents values that are tax exempt.

Source: Ministry of Finance of Slovenia.

199. **A special tax treatment for student income exists.** Students under 26 who earn income from temporary or occasional work can benefit from a special tax allowance. In 2017 (taking effect on 1 January 2018), the special personal tax allowance for student work was increased from 70 % to 100 % of the general allowance and amounts to EUR 3 302.7. Since February 2015, certain SSCs are paid on student work. These include employee and employer SSCs for pension and disability insurance (8.85% and 15.5%), employer SSC for health (6.36%) and employer SSCs for injury at work (0.53%).

Two different regimes exist for the taxation of personal business income

200. **Personal business income can be taxed under the regular regime which allows for the deductibility of actual costs incurred or under the flat-rate regime.** In the actual costs regime, tax losses can be carried forward indefinitely (subject to some limitations, such as non-performance businesses). In the flat-rate regime losses cannot be carried forward (or backward). The actual cost regime is the regular regime; taxpayers can choose to be taxed under the flat-rate regime if certain conditions are fulfilled.

- Under the actual costs regime, the base for taxation is the profit derived by deducting actual costs from actual revenues. In that regime taxpayers can use tax deductions and/or allowances, and must keep appropriate books and records. The net business income (profit) computed with the actual costs regime is subject to the progressive PIT rates schedule (Table 4.1). In 2016 the effective tax rate for taxpayers in this regime was 4.1% but 66% of taxpayers had an average effective tax rate of less than 2%.
- Under the flat-rate regime (also called the 20:20 regime), actual business income is reduced by a presumptive amount of costs equal to 80% of business income irrespective of actual costs incurred; businesses that have low costs clearly benefit the most from the flat-rate regime. The net income is taxed at a 20% rate which results in a 4% effective PIT rate. No other allowances relating to business activity or personal allowances can be deducted. The taxpayer needs to meet the following conditions:
 - Income from activities in the previous fiscal year does not exceed EUR 50 000. In this case the nominal expenses in the amount of 80% of income shall be considered but not more than EUR 40 000.
 - Income from activities in the previous fiscal year does not exceed EUR 100 000 and the taxpayer covered full-time compulsory insurance for at least one person for an uninterrupted period of at least five months. In this

case the nominal expenses in the amount of 80% of income shall be considered but not more than EUR 80 000.

201. **Most self-employed choose the actual cost regime.** There were 111,600 self-employed taxpayers in 2017, of which 66,400 are self-employed under the actual cost regime and 45,200 under the flat-rate regime. However, the number of self-employed under the flat-rate regime is increasing. Compared to 2016, the number of taxpayers under the flat-rate regime increased by 18% (+32% from 2015 to 2016) while the number of self-employed under the actual cost regime declined by more than 7% (-6% from 2015 to 2016). In 2016, the amount of PIT collected under the actual cost regime (EUR 56 million) is higher than under the flat-rate regime (EUR 28 million) (Table 4.7). The self-employed which choose for the flat-rate regime operate in the following sectors: legal/accounting jobs, arts, IT and communication, and manufacturing. The actual cost regime is chosen by the self-employed who operate in the construction sector, wholesale and retail trade, manufacturing, legal/accounting jobs, transportation, and accommodation and food.
202. **In the actual costs regime, the self-employed who operate in the cultural sector benefit from a special tax treatment.** Self-employed who operate in the cultural sector benefit from a reduction in the tax base of 15% up to EUR 25 000. The same special tax relief applies for journalists and athletes.

Table 4.7. PIT revenues levied from the actual regime are higher than the flat-rate regime

| | Mean EUR | | Total EUR Millions | |
|------------------|------------------|---------------|--------------------|---------------|
| | Flat-rate regime | Actual regime | Flat-rate regime | Actual regime |
| Labour costs | 13,556 | 10,646 | 322 | 483 |
| Gross income | 12,719 | 10,390 | 302 | 471 |
| Business | 5,981 | 8,420 | 142 | 382 |
| Salary | 4,390 | 966 | 104 | 44 |
| Capital | 525 | 129 | 12 | 6 |
| Allowances | 3,534 | 7,611 | 84 | 345 |
| PIT | 1,194 | 1,240 | 28 | 56 |
| SSC Employee | 1,144 | 317 | 27 | 14 |
| SSC Employer | 837 | 256 | 20 | 12 |
| % PIT (of Gross) | 9% | 12% | 9% | 12% |
| % Tax Wedge | 23% | 17% | 23% | 17% |

Note: In a very small number of erroneous cases, taxpayers report being in both schemes. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

4.2.2. PIT allowances are numerous

203. **Tax allowances narrow the PIT base considerably.** The PIT system in Slovenia includes many tax allowances (Table 4.8). Generous tax allowances come at a significant tax revenue cost, increase complexity, create distortions and may be more beneficial to richer than poorer households. Countries that have generous tax allowances often have very high tax rates in order to compensate for the revenue cost. Certain allowances are common practice in the OECD countries such as employee SSCs which are deductible from taxable PIT or tax provisions for third pillar private pension savings. Nevertheless, there is significant scope in Slovenia to broaden the tax base.

Table 4.8. Tax allowances and tax exempt income in Slovenia in 2018

| | Amount (EUR) |
|--|--|
| General allowance | 3 302.7 |
| Additional general tax relief for low income ¹ | |
| <i>Income up to 11 166.37</i> | <i>3 302.70 + 3 217.12 (max 6 519.82)</i> |
| <i>Income between 11 166.37 and 13 316.83</i> | <i>3 302.70 + (19 922.15 - 1.49601 x income)</i> |
| <i>Income above 13 316.83</i> | <i>3 302.70</i> |
| Personal allowance | |
| <i>For disabled person</i> | 17 685.84 |
| <i>For student</i> | 3 302.70 |
| For dependents | |
| <i>First dependent child</i> | 2 436.92 |
| <i>Second dependent child</i> | 2 649.24 |
| <i>Third dependent child</i> | 4 418.54 |
| <i>Fourth dependent child</i> | 6 187.85 |
| <i>Fifth dependent child</i> | 7 957.14 |
| <i>The sixth and subsequent children</i> | +1 769.30 |
| <i>Disabled child</i> | 8 830 |
| <i>Other dependent family member</i> | 2 436.92 |
| Other | |
| <i>Special deduction for voluntary additional pension insurance payments</i> | Up to 24% of the mandatory contributions for the pension & disability insurance (max 2 819.09) |
| <i>Credit for pensioner (% of pension)</i> | 13.5 |
| Tax exempt income | |
| <i>Transport to work allowance³</i> | 945 ² |
| <i>Meal allowance³</i> | 893 ² |
| <i>Performance bonuses (13th salary)⁴</i> | |
| <i>Annual bonuses⁴</i> | |

Note: ¹The additional general tax relief for low income has changed on January 1, 2018. A taper rate of 1.49601 has been introduced for income between EUR 11 166.37 and EUR 13 316.83. ² These are average by employee for 2017. Table 4.4 provides more detailed information. ³ Both the transport to work and the meal “allowance” are average amounts of exempt income. ⁴ As of 1st of January 2018, up to 70% of the average wage is exempt from the income tax (up to 100% in 2017), but not from SSCs.

Source: Ministry of Finance of Slovenia.

204. **Many countries have turned their tax allowances into tax credits.** The main argument in favour of tax credits, which are deductible from tax liability while tax allowances are deductible from taxable income, is that the value of tax credits is independent of income while the value of tax allowances is increasing in the taxpayer’s marginal tax rate and so tax allowance benefit higher incomes more (OECD, 2006_[32]).

205. **Various PIT base broadening opportunities exist including the tax treatment of transport costs in relation to work, which is overly generous and has negative environmental effects.** As pointed out, the reimbursement of expenses incurred in relation to work-related travel, including transportation costs to and from work, is not taxed under the PIT. These tax provisions were installed in a context of limited transport infrastructure in Slovenia. However, the policy rationale for this generous tax treatment has become weak. Moreover, it stimulates transport and commuting, and therefore creates negative environmental effects. The current tax regime in relation to work travel should be revised. As the basic tax allowances in the PIT are generous, there seems no need to complement it with an additional allowance for transport expenses. In fact, the

main policy rationale for the basic allowance in the PIT is that it covers the minimum costs incurred to earn taxable labour income; this includes work-home travel (and meal allowance). Any remuneration for transport costs or food at work should be treated as taxable personal income. In addition, the meal allowance could be treated as regular taxable income under the PIT and SSCs. Moreover, the performance bonuses and annual bonuses, which are currently tax exempt up to the average wage, could be taxed as regular income under the PIT. Slovenia should also evaluate whether some of the fringe benefits which are tax exempt could be brought within the reach of the tax system .

206. **Slovenia should continue with its plans to include a tax expenditure report as part of its annual budget cycle to inform policy makers of the tax expenditure costs.** Tax expenditure reporting assists in the management of the overall fiscal position and budget allocations. It involves the estimation of the tax revenue foregone of tax expenditures. This allows governments to assess whether the tax expenditure meets its objectives compared to the cost involved. More generally it can serve for the evaluation of public policies. Tax expenditure reporting also enables the distributional assessment of tax relief across different taxpayers and helps increasing transparency of government policies.

207. **Reducing allowances would significantly increase revenues.** To simulate the impact of reductions in tax allowances (personal allowance, family allowance, etc.) on PIT revenues, allowances on the tax records are reduced to 95%, 90%, 85%, 80% and 75% and substituted into estimated taxable income (Figure 4.11). According to the analysis, reducing tax allowances by 5%, 10% and 15% could increase PIT through higher taxable incomes by EUR 58 million, EUR 120 million, EUR 184 million, EUR 251 million and EUR 319 million respectively.

Figure 4.11. Relatively small reductions in allowances could change PIT significantly

Note: All taxpayers included. Not all tax allowances are available on the tax records such as the child allowance. The analysis assumes no behavioural change and linearity. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

4.2.3. Tax provision for families with children are generous

Slovenia provides both tax allowance and cash benefits for children

208. **In addition to child tax allowances (see Table 4.8), Slovenia also has a system of (tax-exempt) child cash transfers** (OECD, 2018_[33]). The cash benefits are calculated for each child separately according to the level of net family income per family member (over 8 income classes), the ranking level of the child (3 levels: first, second, third and any subsequent child), and the school level (primary, secondary) (Table 4.9). In 2017, the maximum annual cash benefit for children in primary school in a two-parent family was EUR 1 371.72 for the first child, EUR 1 508.76 for the second child, and EUR 1 646.16 for the third child (or subsequent child). For children living in a one-parent family, the cash benefit is increased by 30% and by 20% when a pre-school child does not attend childcare.

Table 4.9. Child cash benefits are generous

Monthly cash benefits for a child from birth to the end of primary school in a two-parent family, 2017

| Number of income bracket | Net family income per family member as a percentage of the average net wage | 1st child | 2nd child | 3rd and subsequent child |
|--------------------------|---|-----------|-----------|--------------------------|
| 1 | Up to 2 225.15 | 114.31 | 125.73 | 137.18 |
| 2 | 2 225.15 – 3 708.58 | 97.73 | 108.04 | 118.28 |
| 3 | 3 708.58 – 4 450.29 | 74.48 | 83.25 | 91.98 |
| 4 | 4 450.29 – 5 192.01 | 58.75 | 67.03 | 75.47 |
| 5 | 5 192.01 – 6 551.82 | 48.04 | 56.06 | 64.03 |
| 6a | 6 551.82 – 6 922.68 | 30.44 | 38.10 | 45.71 |
| 6b | 6 922.68 - 7 911.63 | 30.44 | 38.10 | 45.71 |
| 7 | 7 911.63 – 10 136.76 | 22.83 | 30.44 | 38.10 |
| 8 | 10 136.76 – 12 238.32 | 19.88 | 27.50 | 43.11 |

Note: Transfers for children in the seventh and eighth income classes have been re-introduced as of January 2018. This is a temporary measure, which applies up to the year following the year in which economic growth exceeds 2% of gross domestic product. The monthly amounts of child benefit for a child included in the secondary school (but only for the child younger than 18) in the income bracket 6b increased to: EUR 43.44 for 1st child; EUR 51.10 for 2nd child; EUR 71.17 for 3rd and subsequent child.

Source: (OECD, 2018_[33]).

209. **Housing cash benefits are paid to low-income families.** Married couples with two children at low levels of income can receive significant housing benefits in addition to their family/child cash benefits (Figure 4.12). While family/ child cash benefits are large, also the additional housing cash benefit results in considerable additional income for low income households. Cash benefits are reduced when income rises, but at modest rates. For instance, families at average earnings continue to receive significant child and housing benefits (Figure 4.12).

Figure 4.12. Child and housing benefits are generous

Married couple with two children with the second earner at 67% of the AW, by % of the AW, in 2015

Note: This chart takes into account the child allowance.

Source: Benefits, Taxes and Wages Dataset.

Child tax allowances and child benefits reduce the tax burden for families with children significantly

210. **Child cash benefits and child tax allowances significantly lower the net personal average tax rate for families, especially at lower incomes.** For instance, the net personal average tax rate for a one-earner married couple with two children is 2.6% at 67% of the AW, 12.3% at the AW and 27% at 167% of the AW (Figure 4.13). It is significantly lower than for single taxpayers without children; the difference in effective tax rates ranges between 32 percentage points at the lower end of the income distribution and 7 percentage points at higher income levels (Figure 2.5). The difference in the net personal average tax rate for single taxpayers without children and one-earner married-couples with two children at AW earnings in Slovenia is 21 percentage points, which is amongst the highest in the OECD (Figure 4.14). Poland (at 30 percentage points) and the Czech Republic (at 23 percentage points) subsidise children even more strongly than is the case in Slovenia.

211. **The net personal marginal tax rate increases step-by-step but shows peaks at income levels where the cash benefits are reduced** (Figure 4.15). Peaks are observed at 60%, 105%, 130%, 157% and 208% of the AW. Single taxpayers without children and one-earner married couples with 2 children face the same net personal marginal tax rate at gross earnings above 160% of the AW; this result does not apply to the net personal average tax rate because of the impact of child tax allowances (Figure 2.5).

Figure 4.13. Cash benefits reduce the net personal average tax rate for families with children

Average tax wedge decomposition by level of gross earnings expressed as a % of the AW, one-earner married couple with two children

Source: OECD Taxing Wages 2018.

Figure 4.14. The difference in the tax burden between a married one-earner couple with two children and a single taxpayer without children at the AW is very high

Income tax plus employee contributions less cash benefits as % of gross wage earnings, by family-type earning 100% of the AW, 2017

Source: OECD Taxing Wages.

Figure 4.15. The net personal marginal tax rates are high at income levels where cash benefits are reduced

Marginal tax wedge decomposition by level of gross earnings expressed as a % of the AW, one-earner married couple with two children

Source: OECD Taxing Wages 2018.

Child tax allowance and cash benefits reduce incentives for second earners to participate in the labour market

212. **Tax and cash benefits targeted at children create a disincentive for second earners to participate in the labour market and to work more hours.** The net personal average tax rate for a second earner at 67% of the AW in a married couple with 2 children with a partner (the principal earner) at 100% of the AW is 43% in Slovenia, which is very high compared to average tax rates for second earners in other OECD countries (Figure 4.16). In contrast, a second earner without children in Slovenia faces an average tax rate of 34%. The high net personal average tax rate for second earners is a combination of the high employee SSCs and PITs in Slovenia and because the principal earner who claims the child benefits and child tax allowances will lose some of the advantages when the second earner starts working because of the increase in family income. This loss is added to the tax burden of the second earner and therefore results in significant reduced work incentives.

Figure 4.16. Second earners are not encouraged to work in Slovenia if they have children

Net personal average tax rate for second earners at 67% of the average wage, with principal earner at 100% of the AW, 2015

Source: (Thomas and O'Reilly, 2016^[34])

The design of the child tax allowances and cash benefits is complex

213. **Most countries, including Slovenia, lower the net personal average tax rate for families with children through a combination of PIT reductions and cash transfers** (Table 4.10). Five countries provide PIT reductions only; nine countries only provide child benefits. The Netherlands is the only country which reduces employee SSCs for families with children (OECD, 2018^[33]). Whether to choose for cash transfers and/or PIT reductions depends on different factors. Cash transfers can reach individuals who do not file a tax return. On the other hand, PIT relief for children does not require government to create a separate cash transfer system.

Table 4.10. Most countries lower the net personal average tax rate for families with both a reduction in PIT and cash transfers

Decomposition of differences in net personal average tax rate, number of countries

| | Number of countries |
|---|---------------------|
| Reduction in PIT only | 5* |
| Cash transfers only | 9** |
| Reduction in PIT + Cash transfers | 17 |
| Reduction in PIT + Cash transfers + Reduction in employee SSC | 1 |

Note: Three OECD countries (Australia, Iceland and Mexico) have not been included as the net personal average tax rate is the same for married couple whether or not they have children. * Korea, Portugal, Spain, Turkey, the United States. ** Canada, Denmark, Finland, Ireland, Japan, Luxembourg, Norway, Sweden, United Kingdom.

Source: (OECD, 2018^[33]).

214. **The design of the support for children in Slovenia is complex and not very transparent regarding the overall benefit they provide across incomes.** One the one hand, the cash transfers are decreasing in family income (Table 4.9). On the other hand, the tax allowances for children are constant (although higher allowances are available for each extra child) (Table 4.8) and, as is typically the case with tax allowances, their value is increasing in taxpayer's income.

215. **Slovenia should consider whether the current system of support for children could be reformed. Different reform options exist.** The tax allowances could be turned into tax credits. Alternatively, the current tax allowances could be abolished and replaced by higher cash benefits for children. As Slovenia has a condensed wage distribution, the cash benefits could be provided to all families irrespective of their income level. Such an approach would prevent that marginal tax rates would be increased when the benefits are tapered out. This would also tackle one of the underlying causes of the high tax burdens, and therefore reduced work incentives, for second earners in Slovenia. Alternatively, the cash benefits could be reduced at high income levels only in order to limit the impact on work incentives as much as possible.

4.3. Reduce tax disparities between different legal forms

4.3.1. The “flat-rate” regime is too generous and needs to be reformed

216. **Many tax reliefs apply for business income.** Personal business income can be taxed under the regular regime, which allows for the deductibility of actual costs incurred, or under the flat-rate regime, which reduces actual business income with a presumptive amount of costs equal to 80% of business income (see also section 4.2.1). No additional allowances are available under the flat-rate regime. Under the actual costs regime, additional deductions in the form of tax allowances can be claimed, including (non-exhaustive list):

- Tax allowance of 100% of the R&D investment;
- Tax allowance equal to 40 % of investment in equipment and long-term intangible assets;
- For employment of young and older workers: additional reduction in the tax base amounting to 45% of the salary paid to a new employee younger than 26 or older than 55 and previously long term unemployed;
For employment of disabled persons: additional reduction in the tax base from 50% to 100% of the salary of the disabled employee.

217. **SSC treatment differs between unincorporated and incorporated businesses.** The SSC regime for self-employed entrepreneurs was described in section 3.4. While it is overall very similar to the tax regime for regular employees, including manager-owners of closely held corporations, the main difference is the SSC ceiling for the self-employed which does not apply for regular employees.

The flat-rate regime distorts the labour market and leads to tax evasion

218. **The flat-rate regime was created to stimulate entrepreneurship.** The flat-rate regime was introduced in 2013 during the economic crisis to encourage individuals to start their own business. The main objective of the regime was to lower the tax administrative burden for small businesses – there is no requirement to keep books of accounts but only records – and to provide more transparency and certainty about future tax liabilities.

219. **The number of taxpayers within the flat-rate regime is steadily increasing.** The number of taxpayers increased from 14% of self-employed businesses to 35% in 2016 (which represents around 38 300 taxpayers) (Ministry of Finance of Slovenia, 2016_[35]). In 2015, up to 55% of businesses fulfilled the criteria to be taxed under the flat-

rate regime. This shows that many more businesses could potentially choose to be taxed under the flat-rate regime.

220. **The flat-rate regime induces self-employed entrepreneurs to conceal their income.** An in-depth evaluation of the regime by the Ministry of Finance has found that the regime induces taxpayers to under-report their income below EUR 50 000 in order to qualify for the regime (Ministry of Finance of Slovenia, 2016^[35]). Stricter tax enforcement therefore seems justified, although this increases the risk that the regime will induce taxpayers to work less in order to stay below the income threshold.
221. **The flat-rate regime distorts the functioning of the market.** The regime can cover hidden employment relationships. Bogus self-employment (people forced to take that business status to work for an employer) is estimated to have doubled from 3.8% of total employment in 2012 to 6.6% in 2015 (European Commission, 2017^[27]). The flat-rate regime is particularly vulnerable to be misused for these purposes. Slovenia has attempted to deal with these challenges by introducing anti-avoidance provisions in the flat-rate system in 2017 (with effect as of January 2018) (see Box 1.1). However the reduction of the 80% cost rule (to 60% or 70%) was not implemented.
222. **The flat-rate regime needs to be reformed**, in particular because the effective tax burden under the regime is very low (at 4% effective rate on income) and because it induces businesses not to grow – or to split up their business – in order to qualify for the regime. Several reform options could be considered:
- The presumptive costs of 80% of income could be lowered significantly; in addition, the low tax rate of 20% could be increased.
 - The regime could be phased out over time. This would ensure that the flat rate regime is used for individuals to start a business only but, once the business has proven to be economically viable, the self-employed would be taxed under the regular regime.
 - Another option would be to abolish the flat-rate regime but, instead, (continue to) provide self-employed a temporary cut in SSCs or a PIT credit for the first years after having created a business.

4.3.2. Entrepreneurs face a tax-induced incentives to incorporate

223. **The significant difference in the tax burden on labour and capital income creates tax-induced incentives for business owners to incorporate.** The tax burden on labour income in Slovenia is very high as a result of the combined effect of PITs and high SSCs, as discussed earlier in this report. Although the self-employed can lower their effective PIT burden if they choose for the flat-rate regime, they will continue to face the high self-employed SSCs. The SSC ceiling for the self-employed reduces the tax burden on labour income, but the ceiling hits at 350% of the AW only. The tax burden on capital income is significantly lower (see Chapter 6). While top wage earnings are taxed at a top PIT rate of 50%, the tax rate on distributed dividends at the individual level is 25% only (39.25% if the CIT is taken into account as well). These differences in the tax treatment of labour versus capital income create a strong incentive for self-employed businesses to incorporate their business. In order to minimise their tax liability, managers-owners of closely-held corporations then face an incentive to pay a low wage only and to get the remuneration the form of dividends. Alternatively, they can retain the profits within their corporation and distribute them later or realise the capital gains when they sell the shares in their business.

224. **In order to limit this type of tax-arbitrage behaviour, countries may want to oblige manager-owners of closely held corporations to pay themselves a “minimum” wage.** In Belgium, for instance, manager-owners have to pay themselves a salary of at least EUR 36 000 (IMF, 2017_[36]) and this wage has recently been increased even further. Slovenia requires closely-held corporations to pay their manager-owners a “minimum” wage of only 54% of the AW. This is low and creates many opportunities to actively engage in tax arbitrage opportunities to limit overall tax liabilities.
225. **Closely-held corporations face a tax-induced incentive to accumulate funds within their corporation.** The capital gains tax rate which is levied on realised capital gains is reducing in the holding period of the shares (see Chapter 6). If the shares are held for more than 20 years, no capital gains tax has to be paid. As a result, manager-owners of closely-held corporations can reduce the tax burden to the CIT levied on retained profits. The very high level of wealth that is kept within businesses (Figure 4.17) seems to confirm that these types of tax-arbitrage behaviour are actually occurring in practice.
226. **Indeed wealth held in self-employed business - regardless of whether the business is incorporated or not - is substantial in Slovenia.** In households with a self-employed head of household, self-employment wealth is three times higher than average holdings of self-employment wealth across the entire population (60% of total real wealth vs. 20%) (Figure 4.17). This is above the average: the households where the head of household is self-employed hold 33.9% of their total gross wealth inside their self-employed business, compared to 10.1% on average in the total population. As the number of self-employed remains around 10% of total employment, this likely suggest that most of the wealth is held in incorporated businesses.

Figure 4.17. Wealth held in self-employed business is substantial in Slovenia

Source: (OECD, 2018_[37])

227. **Several options exist for reducing the tax-induced incentives for businesses to incorporate.** First, the “minimum” wage which manager-owners of closely-held corporations have to pay could increase considerably. Currently the threshold is set at 54% of the average wage. Slovenia should consider raising that level to (at least) the AW. Further efforts might be welcome to better align the tax burden on capital and labour income. Reducing the top PIT rate of 50% and increasing the taxes on capital

income at the individual level (see Chapter 6) would be an integral part of such a reform. Another option would be to introduce a capital gains tax which is constant over time and does not decrease with the holding period. This option, however, would not enable taxation of income of non-residents in Slovenia, as, under tax treaties, such capital gains are usually taxed only in the residence jurisdiction.

4.4. Main recommendations

Box 4.3. Recommendations to strengthen the design of the PIT

Objective: Redesign the PIT rate schedule

- Abolish the top PIT rate bracket and rate of 50%
- Increase the PIT rates in the second, third and fourth tax bracket and evaluate the design of the PIT brackets in response to a significant cut in employee SSCs
- Evaluate the impact of the multiple basic tax allowances, and their taper rates, on personal marginal tax rates and work incentives
 - Possibly integrate the additional basic tax allowance (which is reduced when income rises) within the main basic allowance and increase the bottom PIT rate of 16% to offset the impact on higher incomes

Objective: Broaden the PIT base

- Enlarge the PIT base by abolishing the tax exemption for:
 - Annual bonuses
 - Remuneration for home-work transportation costs
 - Meal allowance during work
- Tax fringe benefits as much as possible as regular income
- Turn tax allowances into tax credits

Objective: Redesign the provisions that provide support for children

- Consider increasing the generosity of the child transfers and abolishing the child tax allowances
- If the current design mix of both tax provisions and cash benefits for children is maintained, turn the child tax allowances into child tax credits
- Consider turning the cash benefits into amounts that do not vary with the taxpayer's income to prevent distortions in work incentives; alternatively, phase out the child benefits at high incomes only

Objective : Reduce tax disparities between different businesses legal forms

- Reform the flat rate regime
 - Reduce the 80% assumed costs significantly while increasing the 20% tax rate
 - Introduce a time limit so that the self-employed can only benefit from the regime during the first year's after the start-up of the business
 - Alternatively, abolish the flat rate regime but, instead, maintain for a certain length of time a reduction in SSCs when a new self-employed business is created
- Reduce tax-induced incentives to incorporate
 - Increase the “minimum” wage that manager-owners of closely held corporations have to pay to, at least, the average wage
 - Align the tax burden on labour and capital income (see also Chapter 6) by
 - Lowering the top PIT rate levied on wage earnings
 - Increasing the tax rate on dividends at the individual shareholder level
 - Increasing the capital gains tax rate and do not lower the rate for longer

holding periods for closely-held corporations

Objective: Improve transparency

- Publish an annual tax expenditure report, make it publicly available and develop its scope and content gradually over time

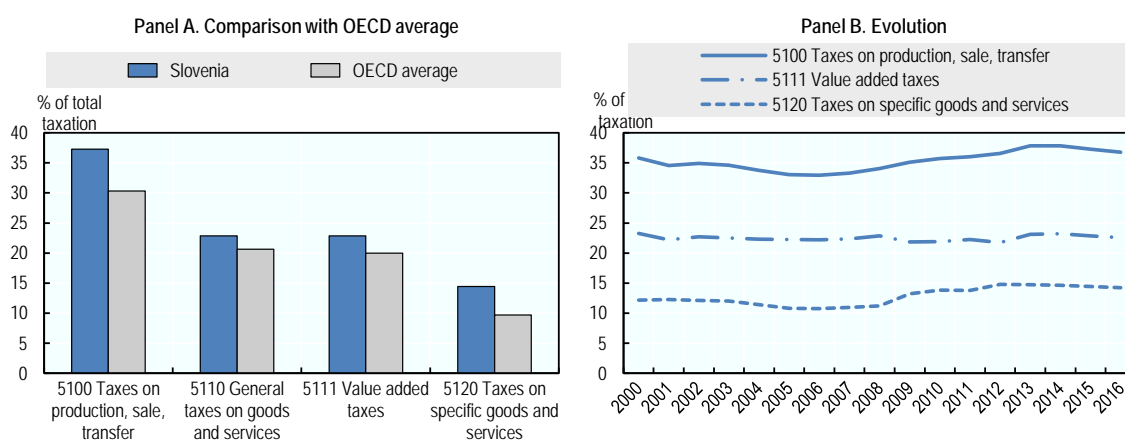

Chapter 5. Improving the design of indirect taxes

Slovenia's tax mix relies heavily on consumption taxes. The standard VAT rate is high and the reduced VAT rate, which is relatively low, applies to a large number of goods and services. As the VAT rate in neighbouring countries is somewhat lower than in Slovenia, increasing the standard VAT rate might come at significant costs in terms of cross-border shopping. Instead Slovenia should keep its standard VAT rate at its current level. However, there is scope to address regressive distributional effects of the reduced VAT rate in Slovenia. Some of the products and services which are taxed at the reduced VAT rate benefit the rich more than the poor both in relative and absolute amounts. This is the case for cultural activities, hotels, restaurants, and air transport. Over time and when neighbouring countries would continue to increase their rates, there might be some scope to further increase excise duties, in particular on alcohol and tobacco.

5.1. Slovenia has a standard VAT rate above the OECD average levied on a narrow base

228. **Slovenia raises a significant amount of revenue from consumption taxes.** As discussed in Chapter 1, Slovenia's tax structure is tilted towards consumption taxes (40 % of total revenue in 2016). Among consumption taxes, Slovenia relies mainly on value added taxes (22.6 % of total revenues) and taxes on specific goods and services (14.2 % of total revenues) (Figure 5.1 Panel A). Their shares have slightly increased over time (Figure 5.1 Panel B). In this context, scope to increase revenues from consumption taxes exists but is limited.

Figure 5.1. Slovenia levies a high amount of revenues with consumption taxes

Note: Panel A: 2015 data. Source: OECD Tax Database.

229. **Slovenia's standard VAT rate is above both the OECD and the EU averages.**

Slovenia has increased its standard VAT rate in 2014, from 20% to 22% (Figure 5.2 Panel A). It is above the OECD average (19.2%). The standard VAT rate in Slovenia also exceeds the rate in neighbouring countries such as Austria or the Slovak Republic (20%) and other South East European economies where it ranges between 17% and 20%. The rate is equal to the rate in Italy, and lower than in Hungary (27%) (Figure 5.2 Panel B). As the VAT rate is relatively high, Slovenia should not aim at raising the rate further but instead maintain it as its current level.

230. **Slovenia's reduced VAT rate applies to a large number of goods and services** including food, non-alcoholic beverages, supply of water, medicines, hotel accommodation, restaurants, etc. The reduced VAT rate was 8% in 2001, and increased to 8.5% in 2002 and to 9.5% in 2013. The reduced VAT rate applies to 22 categories of goods and services, similarly to the Czech Republic, but the VAT base is narrower than in Austria, Hungary, Italy, and the Slovak Republic (Table 5.1). In 2016, tax expenditures related to the VAT reduced rate amounted to EUR 745 million (Ministry of Finance of Slovenia).

Figure 5.2. Slovenia's standard VAT rate is relatively high

5.2. Scope exists to improve distributional outcomes of the VAT system

231. **VAT payments as a share of disposable income are regressive**, on average, (Figure 5.3 Panel A) as the VAT burden decreases with disposable income. These results are driven by household savings as saving rates tend to increase with income. As a result, higher income households tend to have proportionately less of their income subject to VAT in the current year and therefore pay less VAT as a proportion of income in the current year than poorer households (OECD/KIPF, 2014_[38]).

232. **VAT payments as a share of expenditure are slightly progressive** as the VAT as a share of pre-tax expenditure across income deciles shows a progressive pattern on average (Figure 5.3 Panel B). This approach removes the influence of borrowing and saving. Both Slovenia and OECD averages are slightly progressive. This result is a result of the fact that higher income households tend to spend a greater share of their expenditure on standard rated goods and services rather than on reduced (or exempted) items.

Figure 5.3. The VAT as a share of pre-tax expenditure is progressive

Note: The "average" results are a simple average for the 20 OECD countries examined in OECD/KIPF (2014).

Source: OECD/KIPF "Distributional Effects of Consumption Taxes in OECD Countries" (2014).

233. **The reduced VAT rate provides significant support to richer households, but the overall effect remains progressive** (Figure 5.4). Households in each decile gain from the reduced VAT rate but households in the higher income/expenditure deciles benefit more in absolute amounts. The top income decile receives a tax expenditure that is more than double (triple in the case of the top expenditure decile) than what the bottom decile receives. However while these differences are large, looking at their size relative to household expenditure shows that the poor still gain proportionately more than the rich. This shows that overall reduced VAT rate do have a progressive effect in Slovenia.

Figure 5.4. The reduced VAT rate has a progressive effect in Slovenia

Note: Solid bars present the Slovenia simple average of the household average tax expenditures across income deciles and expenditure deciles. The lines present the same results as a percentage of household expenditure.

Source: OECD Distributional Effects of Consumption Taxes in OECD Countries (2014).

234. **Despite being poorly targeted, reduced VAT rates do have the desired progressive effect when they are introduced for the distinct purpose of supporting the poor but not necessarily in other cases:**

- **Reduced rates aimed at supporting the poor (food; pharmaceutical products; water supply) have a progressive effect in Slovenia.** The reduced rate on food provides the majority of support received by low-income and low-spending households. It has a progressive effect but is not well targeted at poor households, as richer households gain a lot more from the reduced VAT rate on those goods in absolute amounts. It is similar for pharmaceutical products for which the reduced rate tend to benefit the middle income/expenditure households most proportionately. Finally the aggregate tax reduction from the reduced VAT rate on water supply is relatively evenly distributed across the income/expenditure distribution. These trends are similar to what is observed on average in other OECD countries.
- **Reduced rates aimed at supporting cultural activities and social goods are regressive in Slovenia and the benefits for rich households are large.** For books, cinema and museums, the aggregate tax expenditures increase substantially as income/expenditure increases, so as the tax expenditures received. The results for newspapers are more balanced: the reduced rate still has a regressive impact.
- **Finally reduced rates introduced for non-distributional and non-cultural purposes are also regressive in Slovenia (hotel, restaurant, air transport).**

235. Given that redistribution is one of the prime rationales for having reduced VAT rates, Slovenia could reassess the merits of its reduced VAT rate for a range of products and services, and bring within the scope of the standard rate goods currently taxed at the reduced rate but of which the richer gain the most in relative and absolute amounts. This includes hotels, restaurants, air transport, books, newspapers, periodicals and cinema and museum tickets. Table 5.2 presents revenue gains simulations from removing some reduced VAT rates.

236. **The imposition of the VAT increases poverty in Slovenia, but to a lesser extent than on average in other EU countries** (Thomas Alastair, to be published^[39]). The conclusion that the VAT is generally not regressive does not mean that policymakers should not be concerned about its impact on poverty. On average in Slovenia the imposition of the VAT increases the poverty headcount (proportion of the population that are below the poverty line of 50% of median disposable income) by 2.7 percentage points, from 4.2% to 6.9%. This increase is below the OECD average increase (3.1 percentage points) and Slovenia remains one of the countries with the lowest poverty headcount based on net expenditure. Same trends are observed when looking at poverty gap (how much additional expenditure on average is needed to move the poor out of poverty) and poverty severity (taking into account the degree of inequality amongst the poor).

Table 5.2. Broadening the VAT base can raise significant additional tax revenue

| Removing reduced VAT rates on... | Revenue gains | | |
|---|---------------|----------|-------------------------|
| | EUR million | % of GDP | % of total tax revenues |
| All reduced VAT rates | 686.7 | 1.7% | 4.84% |
| Books; admission to shows* | 9.4 | 0.0% | 0.07% |
| Books; admission to shows*; newspapers and periodicals | 27.3 | 0.1% | 0.19% |
| Hotel accommodation; restaurant food | 67.5 | 0.2% | 0.48% |
| Passenger transport** | 16.7 | 0.0% | 0.12% |

Note: Based on 2016 tax rules applied to 2010 household expenditure microdata inflation-adjusted to 2016 values, and assuming no behavioural response by taxpayers to the rate changes. According to the Ministry of Finance of Slovenia, in 2016, tax expenditure related to VAT reduced rate amounted to EUR 745 million. Calculations are based on GDP figures from the Statistical Office of Slovenia for 2016 (EUR 40.418 billion in 2015, current prices). *Admission to shows include: cinema, theatre, concerts, museums, and zoological gardens. ** This includes domestic air transport, but not international air transport.

Source: OECD consumption tax microsimulation models.

5.3. Excise duties can play a bigger role in financing the health system

237. **Revenues from excise duties in Slovenia are high.** In 2017 it represents almost 10% of tax revenues (Ministry of Finance, 2018_[2]) which ranks Slovenia among the countries with a strong reliance on excise taxes (Figure 5.5). The share of excise duties in taxation has progressively increased. In 2012 the specific excise duties were increased for cigarettes and fine tune tobacco (but the ad valorem excise rate decreased) (Krasovsky and Tesche, 2016_[40]). In 2014, excise duties on alcohol and alcoholic beverages were raised by 10 % and 5% for all tobacco products. However, the excise duties on cigarettes and alcoholic beverages in Slovenia remain low in comparison to other countries (Figure 5.6 Panels A and B). In contrast, excise duties on energy products are somewhat higher by international standards (Figure 5.6 Panels C and D) although the effective tax rates on gasoline for road use, for instance, remains in the range of the effective tax rates that can be found in other OECD countries (Figure 5.7). Nevertheless, excise duties on energy products collect a significant amount of tax revenues because of the important international transit traffic going through the country.

Figure 5.5. The revenues from excise duties are high in Slovenia

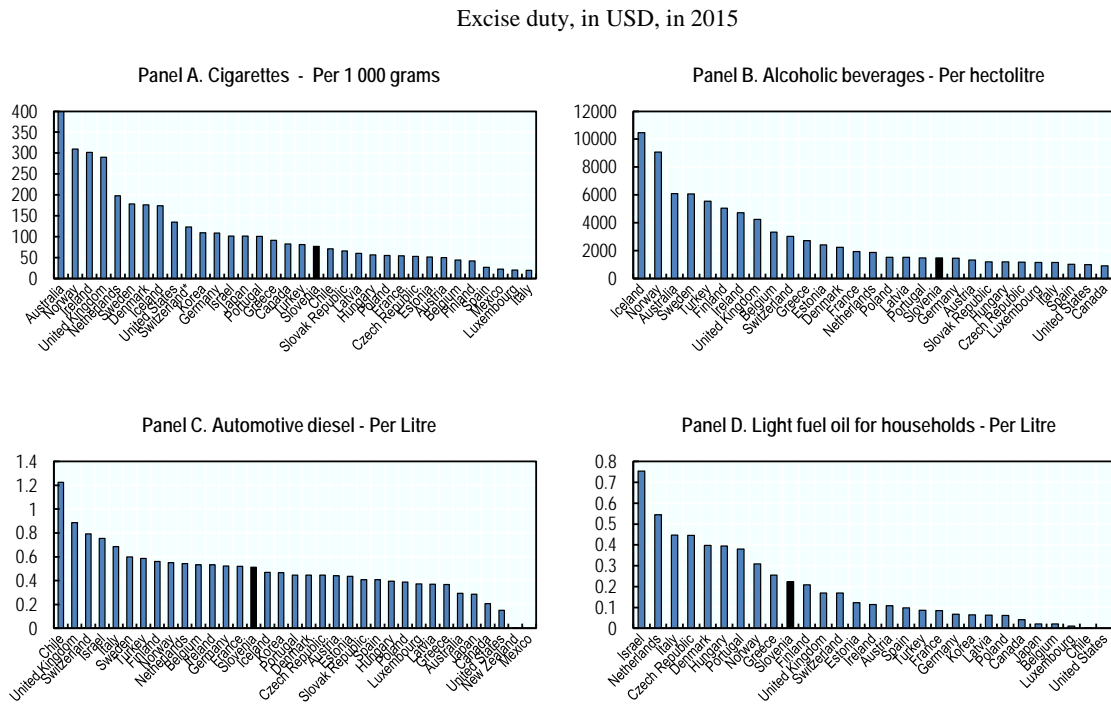

2016 or latest year available

Source: OECD Revenues Statistics database.

238. **Some OECD countries partly finance the public contribution to health care from excise duties on alcohol and tobacco (i.e. so-called sin taxes)** (OECD, 2015^[41]). To some extent, there is a good case for such an approach. Excise duties on alcohol and tobacco internalise some of the costs which the consumption of alcohol and tobacco imposes on society, in particular in terms of extra health expenditure that can be linked to their consumption. There are also other external costs, such as reduced labour market productivity including sick leave, which can be attributed to alcohol and tobacco consumption, although these costs are not necessarily borne by the health system but rather by employers. However strong arguments exist against earmarking of tax revenues. A significant concern is that it reduces flexibility in government budgeting. For example, if more revenue is raised in a particular year from an earmarked tax than is necessary for the related expenditure, the excess revenue cannot be used to address budget shortfalls elsewhere or to finance other budget priorities. While revenues of excise duties on alcohol and tobacco should continue to feed into the general budget, government could consider sharing (part of) its revenues with the HIIS, if such an approach would be necessary to put the financing of the HIIS on a solid footing in the future.
239. **Excise duties on alcohol and tobacco need to be aligned with the excise duties that are levied in neighbouring countries as too high rates will result in cross-border shopping and smuggling.** Recent experience with increases in excise duties in Slovenia have shown that setting rates too high may even lower the revenues collected from excise duties. Slovenia may further increase its excise duties on alcohol and tobacco in particular when neighbouring countries follow the same path.

Figure 5.6. Excise duties on energy products are high compared those on cigarettes and alcoholic beverages in Slovenia

Source: OECD Consumption tax trends.

Figure 5.7. The effective tax rates on gasoline for road use remains in the range of other OECD countries

Source: (OECD, 2018_[42]).

5.4. Main recommendations

Box 5.1. Recommendations to improve the design of indirect taxes

- Maintain the 22% standard VAT rate
- Broaden the VAT base
 - Bring within the scope of the standard rate goods currently taxed at the reduced VAT rate but of which the richer gain the most in relative and absolute amounts (such as hotel accommodation, restaurant food, books, admission to shows, newspapers and periodicals, passenger transport)
- Increase excise duties on alcohol and tobacco, in particular when neighbouring countries increase their rates further

Chapter 6. Strengthening the taxation of capital income at the individual level

The recent move towards the automatic exchange of financial account information between tax administrations creates opportunities for Slovenia to revisit the way it taxes household savings. Tax rates on capital income at the individual level in Slovenia are not particularly high and effective tax rates on household savings vary widely across assets. Some assets, such as owner-occupied and rental immovable property and voluntary private pension savings are taxed particularly lightly. The capital income tax system also lacks progressivity, which is not uncommon under dual income tax systems. Slovenia could consider increasing the progressivity of its capital income tax system. Such a reform will require administrative reform as taxpayers would have to start declaring their capital income annually. Recurrent taxes on immovable property should also play a more significant role in the tax mix in Slovenia. The introduction of the new real estate tax is much-awaited as it creates opportunities to rebalance the tax mix and to reform the financing mix of local governments.

6.1. Slovenia faces modest opportunities to rebalance the tax mix towards higher taxes on capital income at the individual level

240. **Slovenia faces opportunities to strengthen the way it taxes capital income at the individual level.** Households' savings in Slovenia are relatively high compared to other countries. In 2016, Slovenians saved 7% of their disposable income which was in the upper half of the distribution. The analysis in this chapter will show that current tax rates on savings in Slovenia are not particularly high, although effective tax rates vary significantly across asset types. Moreover, the recent move towards the automatic exchange of financial account information between tax administrations creates opportunities to revisit the way countries tax savings as it will be easier to levy taxes on capital income without income and assets necessarily shifting offshore in response (OECD, 2018^[37]).
241. **The shift in revenues from taxes on labour towards capital income might be limited because of relatively low levels of capital income earned.** As labour income constitutes a much large share of total income, any shift from labour to capital income taxes will therefore be modest.
242. **Capital income in Slovenia is highly concentrated in the top income deciles,** suggesting that increasing capital income taxation at the individual level will be borne by the wealthier individuals (Figure 6.1 Panel A). For all percentiles, the vast majority of capital income is comprised of interest income from bank deposits and income dividends. At the bottom of the distribution, the composition is mostly the former while at the top it is mostly the latter. Due to the high level of concentration in the top decile, Panel B presents the capital income distribution for the first 9 deciles. It is seen that, for the first

half of the distribution, interest income from bank deposits typically comprises between half and three-quarters of capital income, with most of the remainder being dividends. Income from capital gains does not start to become a significant component of capital income until after about the 85th percentile. Even if increasing tax rates at higher income levels might strengthen equity, government should keep in mind that taxpayers can vote with their feet if tax rates become too high.

Figure 6.1. Capital incomes are highly concentrated in the very top of the distribution

Note: Analysis only includes taxpayers with capital incomes of at least EUR 100. Capital income is comprised of dividends, capital gains (shares), income from interest on deposits in banks and savings banks (interest on deposit) and income from other interest such as loans and debt securities). Methodological information on the microdata is available in the annex. The total capital income decreases in some percentiles due to identical values for different taxpayers are assigned to the same percentile. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata

6.2. Strengthen the taxation of household savings

243. **Capital income is primarily comprised of income from dividends.** Overall, there is EUR 455 million in capital income in Slovenia and EUR 92 million is collected

in PIT (Table 6.1). The effective rate, defined as PIT as a percentage of income, is 20.2%.

Table 6.1. Capital income is primarily income from dividends

| Capital income, by type, 2016 | | | |
|-------------------------------|------------|-----------|------------------|
| | Income | PIT | % Effective Rate |
| Total capital income | 455 | 92 | 20.2% |
| Dividends | 290 | 70 | 24.3% |
| Capital gains | 92 | 14 | 14.7% |
| Interest on deposits in banks | 58 | 5 | 8.0% |
| Other Interest such as loans | 16 | 3 | 21.3% |

Note: Analysis only includes taxpayers with capital incomes of at least EUR 100. Capital income is comprised of dividends, capital gains (shares), income from interest on deposits in banks and savings banks (interest on deposit) and income from other interest such as loans and debt securities. The effective tax burden on capital is higher than presented here as the analysis does not include corporate income tax. Methodological information on the microdata is available in the annex.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

6.2.1. Statutory tax rates on capital income remain relatively low

244. **Slovenia's statutory CIT rate has increased from 17% to 19% in 2017** (see Box 1.2) **but the rate remains relatively low in international comparison.** While the CIT rate in Slovenia is equal to the rate in the Czech Republic and in Poland, it remains significantly below the average rate in the OECD (23.9% in 2018), although above the rates in other South East European economies where it ranges between 9% and 15%.

245. **Dividends, interest and rental income are taxed at a flat final withholding tax of 25%.** The first EUR 1 000 of interest from bank deposits is tax-exempt. The tax rate on realised capital gains decreases with the length of the period that the asset has been held. The capital gains tax rate is 25% for a holding period up to 5 years; 15% for a holding period from 5 to 10 years; 10% for a holding period from 10 to 15 years; 5% for a holding period from 15 to 20 years and assets that have been held for more than 20 years are tax exempt.

246. **The effective rate on capital income is lower than the statutory tax rate** (Table 6.1) due to different tax rates for capital gains depending on the holding period and the tax exemption up to EUR 1,000 for interest income on bank deposits. Increasing the rate will therefore be more effective at increasing capital income tax from dividends than from capital gains for example. About one-third of taxpayers have a capital gains tax rate of 25% indicating that gains were realised within a five year period (Figure 6.2). 23% of taxpayers paid no capital gains tax suggesting a holding period of 20 years or more.

Figure 6.2. About one-third of taxpayers have a capital gains tax rate of 25%

Income from capital gains, by rate and holding period, 2016

Note: Analysis only includes taxpayers with capital incomes of at least EUR 100. Holding periods are inferred through the effective tax rates that are calculated for each taxpayer in the microdata and categorised. Only tax rates with the rate categories shown are included in the analysis.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

247. **Several other countries tax shareholder income via a final withholding system, including Austria, the Czech Republic, Italy, and Poland.** Under this system, tax is withheld either by the distributing company or by the withholding agent on behalf of the individual shareholder and no further tax is payable at the shareholder level. While such a system reduces tax compliance costs for taxpayers who do not have to declare the dividend income in their annual tax return and tax administration costs, it comes at a cost in terms of tax policy design. Final withholding systems typically levy a flat tax rate instead of taxing dividends at progressive rates and/ or exempting a basic amount of dividend income from tax.

248. **The combined “top” statutory tax rate on dividends in Slovenia is close to the OECD average.** The overall tax burden on capital income consists of the tax rates levied at the corporate and individual level, and takes into account the interaction of the tax rates levied at both investor levels (if any) (Figure 6.3). The combined top statutory rate on dividends is 39.25% in 2018 (taking into account the increase in the statutory CIT rate) (Figure 6.3 Panel A). This rate is close to the average rate of 40.4% in the OECD and below the rates in Italy and Austria although above the rate in the Czech Republic and Hungary (31.2%) (Harding and Marten, 2018_[43]). Combined top statutory tax rates on dividends are lower in some of the other SEE economies. For instance, the rate was 10% in Bosnia and Herzegovina and Kosovo, 27.8% in Albania and Serbia, 19% in the Former Yugoslav Republic of Macedonia, and 17.2% in Montenegro.

249. **The combined “top” tax rates on capital gains are significantly lower than the tax rate on dividends.** The statutory tax rates on capital gains on assets which have been held for more than 20 years in Slovenia are particularly low (Figure 6.3 Panels C and D) because of the capital gains tax exemption; hence only the statutory CIT rate is paid. For shares which are sold earlier, the combined top tax rate on capital gains ranges between the top tax rate on dividends and the statutory CIT rate.

250. **The statutory tax rate on interest income is also relatively low.** Irrespective of the source of interest income (retail bank accounts or corporate bonds), the tax rate is 25%. This is lower than in Austria or Italy but above the rate in the Slovak Republic (19%) and the tax rate in Hungary and the Czech Republic (15%) (Harding and Marten, 2018^[43]). Other SEE economies levy also very low tax rates on interest. The rate is 15% in Albania and Serbia, 10% in Kosovo and the Former Yugoslav Republic of Macedonia, 5% in Montenegro and 0% in Bosnia and Herzegovina.

251. **The combined top statutory tax rates on capital income are significantly lower than the top tax burdens on labour income in Slovenia.** As pointed out in section 4.3.2, the important tax differential between labour and capital income creates significant tax-induced incentives for businesses to incorporate.

Figure 6.3. The combined “top” statutory capital income tax rates in Slovenia are below the OECD average

In %, 1 July 2016

Note: Combined statutory tax rates take into account both the statutory CIT rate (if applicable) and the statutory tax rates on capital income at the individual level (including final withholding tax rates, if any), as well as the interaction of both tax rates (if any). OECD calculations based on questionnaire responses. The rates presented are “top” rates meaning that they take into account the top capital income tax rates levied at the individual level. Panel A: The unweighted mean includes the tax rate on new equity in Italy and in Turkey and not the tax rates on existing equity. Panel C: The unweighted mean includes the tax rate on new equity in Italy and in Turkey and does not include the tax rates on existing equity. If the combined tax rates on existing equity were used, the unweighted average combined rate would be 36.8%. Panel D: The unweighted means does not include the capital gains tax rate for the United States, which varies under a certain number of assumptions.

Source: (Harding and Marten, 2018^[43])

6.2.2. METRs on household savings vary widely across asset types

252. **The effective tax rates on household savings in Slovenia differ from the statutory tax burdens.** Figure 6.4, Figure 6.6 and Figure 6.7 present marginal effective

tax rates (METRs) on a wide variety of saving vehicles. In contrast to the analysis in the previous section, these METRs only include the taxes levied on capital income at the individual level; they do not take into account the CIT. The OECD calculates METRs on household savings to assess the impact of a wide range of taxes and tax design features on the incentives to save in different assets; large differences in METRs reflect significant tax-induced incentives for households to adjust their savings portfolio in order to minimise their capital income tax liabilities. The METR calculations take into account all taxes levied on household savings, deductions and variations in the tax base, different asset holding periods and the potential build-up of untaxed or tax-deferred returns. METRs also incorporate the impact of inflation, which can impose a substantial additional tax on the return to savings.

253. **The taxation of nominal rather than real returns increases METRs considerably.** In 2016, the METR on bank deposits and dividends in Slovenia was 33% rather than the 25% withholding tax rate as a result of the taxation of the inflation component in the return that is earned. The lack of indexing of returns in Slovenia, as is the case in most OECD countries, results in METRs on savings which are increasing in the inflation rate.

254. **Equity-financed investment in owner-occupied residential properties is taxed lightly in Slovenia.** Across the OECD, investment in owner-occupied housing is taxed at low rates (Figure 6.7). The METRs on equity-financed investment in owner-occupied residential property are particular low in Slovenia, although they are even lower in Italy and in the Slovak Republic (Figure 6.4). The effective tax burden on rental properties in Slovenia is higher but remains relatively low compared to other OECD countries (Figure 6.4).

Figure 6.4. Marginal effective tax rates on savings in Slovenia are relatively low

Source: (OECD, 2018_[37]).

255. **Voluntary private pension savings in Slovenia are tax-favoured, especially for richer households.** Many countries provide a special tax treatment to induce households to save for an additional pension. Such a strategy is often justified because of pressures on the financing of adequate pensions in the future often linked of the ageing of

the population. In case private pension savings are deductible (up to certain limits in most countries) from taxable personal income, the marginal effective tax rate is low or even negative as the tax gain that arises because of the upfront deduction offsets the taxes on the return on investment. Negative METRs arise when the tax rate at which pension savings can be deducted is higher than the tax rate at which the pension is eventually taxed. If the value of the upfront deduction of private pension savings increases with the taxpayer's marginal tax rate, METRs will be lower for taxpayers with higher incomes. This is the case in Slovenia, where are indeed higher incomes that benefit the most from the tax treatment of private pension savings (Figure 6.6).

256. **The effective tax rates on interest income (bank deposits and bonds) exceed the rates on capital gains and other tax-favoured saving vehicles.** As interest is not taxed under the CIT while the return on equity is typically taxed at both corporate and individual shareholder level, slightly higher taxes on interest at the individual level may be a way to integrate the differential tax treatment of debt and equity at the corporate level. In EU countries including Slovenia, bank deposits are the most common form of financial asset and make up a larger share of the asset mix for those at the bottom of the income distribution (Figure 6.5). This means that higher levels of taxation of interest on bank deposits hit poorer households more as richer households typically hold a more diversified savings portfolio. Nevertheless, the overall effective tax burden on interest income (Figure 6.4 and Figure 6.6) remains relatively low in Slovenia, in particular when compared to wage earnings. Moreover, the negative distributional impact of higher taxes on interest income in Slovenia has been offset through the EUR 1000 of interest exemption.

Figure 6.5. Bank deposits tend to make up a greater share of wealth for lower-income households in Slovenia

Source: <http://www.oecd.org/tax/tax-policy/taxation-household-savings-slovenia.pdf>.

257. **METRs do not increase with income in Slovenia.** The proportional tax rate on capital income is reflected in METRs that are constant across income levels, with the exception of private pensions (Figure 6.6). Proportional tax rates are a typical characteristic of Dual Income Tax (DIT) systems which are widespread in the OECD.

Some countries, however, tax capital income at the individual level at progressive rates, the effect of which is reflected in the 40-country average results presented in Figure 6.7.

Figure 6.6. The proportional rate on capital income in Slovenia results in METRs which are constant across income except for private pension savings

Source: (OECD, 2018_[37]).

Figure 6.7. Marginal effective tax rates on household savings are increasing with income on average across the OECD

Source: (OECD, 2018_[37]).

6.2.3. Slovenia faces different capital income tax reform options

258. **Slovenia faces several reform options to raise more revenues from taxing capital income at the individual level while increasing the tax system’s progressivity.**

- As combined and effective tax rates on capital income in Slovenia are lower than on average, the flat tax rate of 25% on dividends, interest, and rental income

could possibly be increased slightly. This would raise additional revenues and enhance the overall progressivity of the tax system as richer households typically earn more capital income. Box 6.1 presents estimates of the impact on revenues from an increase in the capital income tax rate.

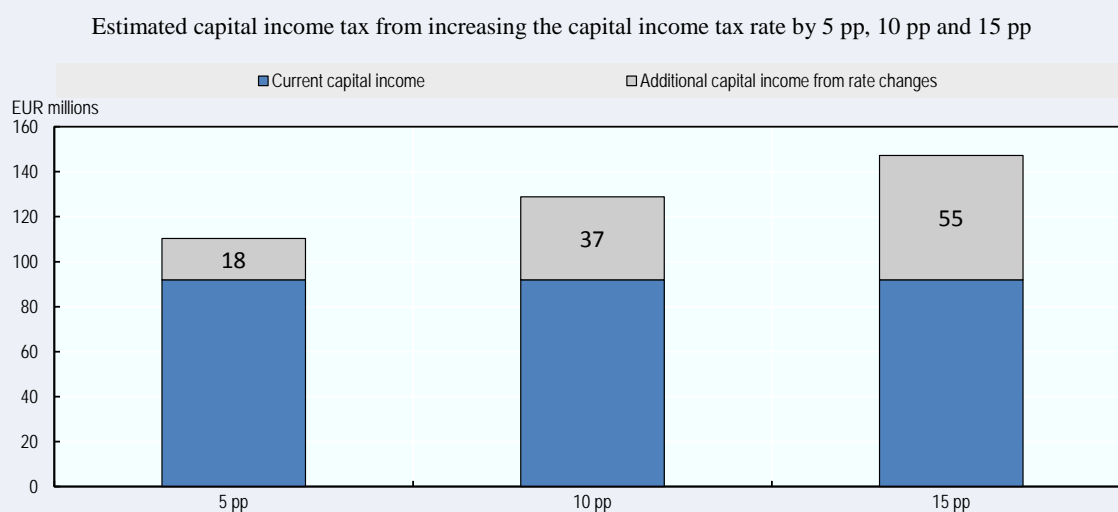

- While the use of a final withholding tax reduces administrative costs, it limits the tax policy design options. While withholding of taxes by third parties remains the best solution to ensure tax compliance, the tax administration should reform its administrative processes such that taxpayers can be asked to file their capital income as part of their annual tax return (as is already the case for interest income from bank deposits). This will allow Slovenia to tax capital income at progressive rates.
- Slovenia could consider broadening the scope of the EUR 1 000 of exempt interest income to other types of capital income including interest on bonds and dividends. This would prevent the current tax-induced distortion against investment in businesses.
- Slovenia could abolish the phasing out of the capital gains tax with the holding period or levy a minimum capital gains tax rate for longer-held assets. While a too high tax rate on capital gains might create lock-in effects in the sense that shareholders would prefer to hold on to their shares instead of realising their gains, a similar distortion arises when the capital gains tax rate is decreasing in the asset's holding period. A minimum capital gains tax rate would also help reducing the tax-induced incentives for self-employed businesses to incorporate and it would reduce incentives to invest in real estate over other types of investment.

259. **In order to increase the progressivity of the tax system, Slovenia could consider moving from a (semi-) dual income tax towards a dual progressive income tax system.** As is the case in many other OECD countries, Slovenia implements a (semi-) dual income tax system. Dual income tax systems tax different types of income separately at different tax rates. Capital income is typically taxed at low (and often flat) rates while labour income is taxed at higher and progressive rates (OECD, 2006_[32]). Dual progressive income tax systems would maintain the separation between capital and labour income, but would tax both types of income at, albeit different, progressive rate schedules.

Box 6.1. Impact of an increase in the capital income tax rate

Total income from capital in 2016 is EUR 455 million and PIT is EUR 92 million, or an effective rate of 20.2%. The analysis shows that increasing the capital income tax rate by 5 pp, 10 pp and 15 pp could cumulatively produce an additional EUR 18 million, EUR 37 million and EUR 55 million respectively (or approximately EUR 18 million for each 5 percentage points increase), assuming no behavioural changes in response to these tax rate increases (Figure 6.8).

Figure 6.8. EUR 18 million can be raised for each 5 percentage points increase of the capital income tax rate

Note: The effective rate is taken as a proportion of the statutory rate (25%), which is assumed to be constant for further rate increases. On this basis, an increase to the rate of 26% for example would only produce about four-fifths of that percentage in PIT (or an effective rate of 21.0%) or EUR 3.7 million. The estimate assumes no behavioural changes in income shifting or compliance and that linearity for higher rate increases.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

260. **The social security tax base could be broadened to include capital income at the individual level.** Box 6.2 presents the example of France where contributions for the social security system are not only levied on wages but on a broader tax base which includes capital income. In designing such a broad based social tax, countries need to take into account that SSCs can be challenging to implement when levied on the income of non-residents. According to a decision of the European Court of Justice in 2015, SSCs cannot be levied on foreigners as they are not entitled to social security benefits in the jurisdiction where they have paid SSCs.

261. **The tax privileges for voluntary (third pillar) private pension savings benefit richer households more.** Taxpayers may deduct voluntary private pension savings from taxable personal income up to 24% of the compulsory contributions for pension and disability insurance with a maximum of EUR 2,819.09 per year (Ministry of Finance, 2018_[7]). Contributions above the cap are not tax deductible (OECD, 2015_[44]). On

average, low incomes in Slovenia do not save very much for a tax-favoured third pillar private pension. Private pension savings constitute 16% to 19% of total financial assets in the top three income deciles while they constitute only 3% to 5% of total financial wealth in the bottom three income deciles (Figure 6.5). In light of the low public pensions and the increasing ageing related costs, Slovenia might evaluate whether the design of the tax privileges for private pension savings is effective. Possible reform options to consider include: 1) express the maximum amount of tax-deductible private pension savings in EUR rather than as a percentage of compulsory pension SSCs; 2) allow the un-used tax privilege to be carried forward over time; and 3) turn the tax allowance into a tax credit such that the value of the tax deduction is similar for low and high income earners.

262. **The recent move towards the automatic exchange of financial account information (AEOI) between tax administrations offers an opportunity to revisit the way countries tax capital income at the individual level.** AEOI will provide information to the tax administration of the capital income earned by tax residents in other jurisdictions. Evading taxes by moving assets offshore and not declaring the income in the jurisdiction where the tax payer is tax-resident is becoming increasingly difficult. AEOI therefore creates opportunities for countries to tax capital income at slightly higher rates than currently is the case and/or to shift part of the capital income tax burden from the corporate to the individual level, without running the risk that assets leave the country in response (OECD, 2018^[37]). However, in order to seize the opportunities created by AEOI, the Slovenian tax administration will have to strengthen its operational framework and data analysis tools in order to be able to process the taxpayer information it will receive from other jurisdictions.

Box 6.2. Broadening the tax base to passive income for financing social security system: the case of France with CSG

In France, the Contribution Sociale Généralisée (CSG) was created in 1990. The CSG is the most sizeable of all the various taxes earmarked for funding social insurance. Contributions are based on all sources of household income (wages, income from financial assets and investments, pensions, unemployment benefits, disability benefits and gambling proceeds) and are withheld at source.

Revenues from the CSG went up from EUR 58 billion in 2000 to nearly EUR 84 billion in 2010, exceeding income tax revenues by nearly EUR 30 billion. The CSG now represents two thirds of earmarked tax revenues for social insurance financing. One of the effects (and advantage) of the CSG is the diversification of sources of funding for social protection which is based on both SSCs and taxes (i.e. the CSG). The CSG has largely replaced regressive contributions based on wages and salaries with a proportional and very broad base contribution based on all sources of household income. In parallel wage-based contributions (primarily levied on employers) have progressively declined.

Contrary to its initial objectives of simplicity and transparency, the CSG has become complex. The CSG has now 6 different rates depending on the types and levels of income (instead of one proportional rate). In addition the CSG combines different progressivity elements whereas at the start it was designed to be strictly proportional. Finally different taxes following the same logic of the CSG (i.e. with the same tax base) have been created without being merged with the CSG (such as social contributions on capital income), thereby further increasing the complexity of the tax system.

Source: (OECD, 2017^[45]); (Cour des comptes, 2011^[46])

6.3. Raise more revenues from taxes on immovable property

263. **Slovenia should strengthen the role of immovable property taxes.** Revenues from property taxes in Slovenia are currently low (0.5% of GDP in 2015) and below the EU and the OECD averages (1.1% of GDP). Slovenia faces a significant opportunity to rebalance its tax mix away from more distortive taxes towards recurrent taxes on immovable property which is considered to be the least distortive tax for economic growth. The new recurrent tax on immovable property, which is scheduled to be implemented over the coming years, creates great opportunities for Slovenia to rebalance its tax mix. Slovenia should consider levying a higher recurrent tax on second houses and holidays homes.

264. **Significant revenues could be raised if revenues from recurrent taxes on immovable property were increased to the average level in the OECD.** Estimations presented in Table 6.2 show that this would increase tax revenues with EUR 280 million (compared to 2015). Table 6.2 also presents how much additional revenues could be raised if Slovenia were to collect revenues similar to the level of the OECD's best performers (the United Kingdom, Canada, France, or the United States), which levy between 2.5% and 3.1% of GDP in revenues from recurrent taxes on immovable property.

Table 6.2. Recurrent taxes on immovable property could raise significant additional revenues

| | % of GDP | EUR billion | Additional revenues raised compared to 2015 (EUR million) |
|------------------------------|----------|-------------|---|
| 2015 (latest info available) | 0.5 | 0.19 | |
| Scenarios | 1.1* | 0.48 | 280 |
| | 2.5** | 1.08 | 890 |
| | 3.1** | 1.34 | 1 150 |

Note: Calculations are based on GDP figures from the Statistical Office of Slovenia (EUR 38.837 billion in 2015; EUR 43.278 billion in 2017, current prices). * OECD average in 2015. ** OECD best performers.

Source: OECD Revenues Statistics.

265. **Slovenian households hold a larger share of their total gross wealth in the form of real assets rather than in the form of financial assets** (OECD, 2018_[37]). The main residence is by far the largest single asset category in Slovenia. Table 6.3 describes the taxes that are levied on occupied and rental property in Slovenia. Rental income is currently taxed at flat 25% tax rate whereas it is typically taxed at progressive rates in other countries. As part of a property tax reform, Slovenia may also want to assess whether it could tax rental income at higher and, possibly, progressive rates.

Table 6.3. Tax treatment of property at different stages

| | Owner-occupied residential property | Rented residential property |
|-------------|--|--|
| Acquisition | No tax relief for mortgage interest paid. Transaction tax only | |
| Holding | No capital income tax on the imputed rental income, but recurrent property tax | Rental income is taxed at flat rate of 25% |
| Disposal | Tax on capital gains (recurrent property tax) phasing out with holding period | |

Note: Capital gains derived by the disposal of immovable property purchased or otherwise obtained before January 2002 are not taxable (Article 153 of PIT Act).

Source: (OECD, 2018_[37])

266. **Distributional analysis indicates that there might be scope to increase the taxes on property rental income in Slovenia.** In 2016, approximately 90,000 taxpayers earned rental income representing EUR 216 million in income and EUR 48 million in tax revenues. Table 6.4 shows a breakdown of income and tax revenues from rent for taxpayers with rental property income by rental income decile. The top 20% of taxpayers pay 80% of property rents. Due to limited deductions on property rent, the proportion of income that is taxable remains approximately stable at 90% across the income distribution. In addition, those with property have relatively high gross incomes. Even those in lower deciles have higher than the average income in the taxpayer population. For these reasons, increasing the PIT on rental property could be both effective and equitable.

Table 6.4. There is scope to increase property rental income

| EUR | | | | | | |
|---------------|---------------------|--------------------|---------------------|-------------------|----------|------------|
| | Number of taxpayers | Mean rental income | Total rental income | Mean gross income | Mean PIT | Total PIT |
| Bottom decile | 8,978 | 5 | 42,563 | 17,462 | 1 | 9,573 |
| 2 | 8,974 | 14 | 122,934 | 17,250 | 3 | 27,605 |
| 3 | 8,974 | 26 | 235,854 | 17,712 | 6 | 52,995 |
| 4 | 8,975 | 51 | 459,445 | 18,487 | 12 | 103,946 |
| 5 | 8,974 | 195 | 1,747,534 | 18,042 | 44 | 398,368 |
| 6 | 8,976 | 760 | 6,821,042 | 17,045 | 167 | 1,495,698 |
| 7 | 8,975 | 1,465 | 13,148,947 | 18,340 | 316 | 2,840,409 |
| 8 | 8,971 | 2,442 | 21,904,071 | 21,885 | 529 | 4,748,545 |
| 9 | 8,979 | 4,123 | 37,018,490 | 24,124 | 906 | 8,138,786 |
| Top decile | 8,975 | 15,000 | 134,627,370 | 38,126 | 3,345 | 30,019,091 |

Note: Methodological information on the microdata is available in the annex.

6.3.1. The revision of the recurrent property tax is on going

267. **The 2013 Real Property Tax Act was annulled by the Constitutional Court in March 2014**, two months after entering into force, and the previous legislation was reinstated. The goal of the reform was to substitute the two existing property tax systems with a unified real estate tax with a tax base linked to the market value of the property using a computer assisted mass appraisal system. The introduction of a revised version of the real estate tax which will broaden the tax base has been postponed until 2019 (European Commission, 2017_[47]).

268. **The current property tax system consists of two taxes which owners of real property have to pay:** the property tax and the “charge for the use of building land” (Ministry of Finance, 2018_[7]). The property tax base for premises (building, apartment, secondary houses etc.) is the value ascertained according to special criteria issued by the government and local communities. The tax rate depends of the type of property (dwellings, premises used for rest and recreation, business premises) and its value. Exemptions include buildings of less than 160 square meters; buildings used for agricultural purposes; business premises used by the owner or user for business activity; and cultural or historical monuments. In addition, a 10-year temporary exemption applies to taxpayers who own a newly constructed building or repaired or renovated buildings if the value of the buildings has increased by more than 50% as a result of the renovation. Finally for a taxpayer with more than three family members who live in the owner's house, the tax decreases by 10 % for the fourth and every additional family member.

269. **The charge for the use of a building land is levied on vacant and constructed building land owned by individuals or legal entities.** It is set by local communities and paid on an annual basis by both individuals and companies. The financial administration collects the tax based on information provided by municipalities.

6.3.2. Slovenia should take the opportunity of the current property tax reform to rebalance the way municipalities are financed

270. **Municipalities rely too strongly on the revenues from the PIT which are shared between central and local government (see Chapter 1).** Financing local governments mainly through revenues from the PIT is uncommon and brings significant

disadvantages. PIT revenues are more volatile than property taxes. It results in large disparities in revenues as municipalities with a larger share of higher-income inhabitants will receive more funding. It also reduces incentives for municipalities to optimally use the recurrent tax on immovable property, which is the main tax used to finance sub-central governments across the OECD.

271. **Raising more property taxes would give financial leeway to the general government to finance a cut in employee SSC.** Additional revenues from recurrent taxes on immovable property could progressively, and partially, replace transferred PIT revenues from the general government to municipalities. As a result, more revenues from the PIT would gradually remain for the general government, which could be used to finance a decrease in employee SSC.
272. **The new recurrent tax on immovable property should be turned into a local tax.** Central government, however, should define the tax base and provides valuation guidance. Municipalities should not receive the power to provide tax exemptions. Central government might also want to set the tax rates within a minimum and maximum band to avoid a race to the bottom type of tax competition. Finally the central government could introduce a fiscal equalisation grant system to provide additional funding to municipalities that are collecting too little revenue from the new property tax. Sharing of PIT revenues with local governments should be kept as limited as possible in order to ensure that municipalities use the recurrent immovable property tax efficiently.
273. **Additional revenues from the recurrent tax on immovable property would allow changing the financing mix of municipalities, away from a very strong reliance on revenues from the PIT.** Recurrent taxes on immovable property are a more stable source of revenues than the PIT, and are therefore the most widely used source of local financing across the world.
274. **The formula that assigns additional tax revenues to municipalities could be lowered and adjusted to take into account the extent to which municipalities face the opportunity to collect revenues from recurrent taxes on immovable property.** The higher the property values in a municipality, the greater potential for that municipality to collect revenues from recurrent taxes on immovable property and the lower the share of PIT revenues it should receive. Such a reform would strengthen the role of property taxes in Slovenia and would allow a significant reduction in the overall share of PIT revenues which are shared with municipalities – currently 54% of PIT revenues are shared – which would free up PIT revenues which could be used to finance other priorities. In 2014, for instance, municipalities received PIT revenues equal to about 3% of GDP (Figure 1.13). Given the current revenues of 0.5% of GDP, an increase in recurrent taxes on immovable property with about 1% of GDP, would allow reducing the overall 54% sharing ratio with one-third to 36%. Raising revenues from immovable property equal to 2.5% of GDP, which is similar to the OECD best performers, would allow reducing the sharing ratio with two-thirds, to 18%. Central government should lower the PIT revenue sharing ratio from 54% to 36% once the recurrent tax on immovable property is put in place and then continue lowering the ratio gradually over time to a ratio between 30% and 18%.

6.4. Main recommendations

Box 6.3. Recommendations to improve the taxation of capital income at the individual level

Objective: Raise more revenues from taxing capital income at the individual level

- Consider increasing moderately the taxes on capital income at the individual level to help finance a cut in employee SSCs
- Consider moving towards a dual progressive income tax system
 - Tax capital income at mildly progressive rates
 - Broaden the scope of the interest exemption (of EUR 1,000) to other types of capital income
- Strengthen the efficiency of the tax-privileges for voluntary third-pillar private pension savings
 - Express the ceiling in EUR rather than linking it to pension SSCs paid
 - Replace the deduction for private pension contributions with a tax credit
- Strengthen the capital income tax administration
 - Strengthen IT tools in order to use information received from foreign tax administrations under the AEOI effectively
 - Make it compulsory for individual taxpayers to declare capital income on an annual basis (as is already the case for interest on bank deposits), but maintain the withholding of taxes at source

Objective: Revise the tax treatment of immovable property

- Tax owner-occupied property at higher rates than currently is the case
- Tax rental income at higher and possibly progressive tax rates
- Implement the real estate tax reform as quickly as possible
- Levy a higher recurrent tax on second houses and holidays homes

Objective: Reform the financing of municipalities

- Turn the new recurrent tax on immovable property into a local tax
 - Ensure that the tax base is set by central government and ensure that local governments can value property according to central government rules
 - No longer allow municipalities to introduce tax exemptions and special tax provisions
 - Set rates within a minimum and maximum band to avoid a race to the bottom type of tax competition between municipalities
 - Adjust the formula that shares PIT revenues such that municipalities with higher valued properties receive less PIT revenues
 - Adjust the fiscal equalisation grants such that municipalities that are not able to collect sufficient revenues from recurrent taxes on immovable property are compensated
- Lower the 54% PIT revenue sharing ratio to 36% once the new recurrent tax on immovable property is operational and continue lowering the ratio gradually over time

Annex

Microdata

275. **The microdata analysis in this paper is based on the Slovenian Financial Administration's administrative income tax records**, which follow the entire population of approximately 1.85 million taxpayers over the period 2015 to 2016. The Slovenian microdata, provided by the Financial Administration, represent the most comprehensive source of information on incomes, taxes and SSCs in Slovenia. For the purposes of the microdata analysis, small amounts of reported gross income are removed below EUR 500, which would otherwise skew the distributional data, which has virtually no effect on total income but reduces taxpayer observations to 1.5 million in each year.¹⁶

Comparison with survey data

276. **Compared with survey data, tax record data have several advantages** (Jenkins, 2001). First, coverage of the full taxpayer population allows for specific sub-group analysis while retaining adequate sample size. Second, it is an offence to submit a false tax return so incomes are mostly free from measurement error such as misreported incomes or response bias. Third, as noted by Jenkins, tax records are often 'used as a validation gold standard against which to assess measurement error in survey-based income data'. For example, it gives a scarce insight into income dynamics at the very top end, where the tax records are more comprehensive.

277. **There are also limitations to administrative data.** For example, the data is confined to those who complete tax returns and does not cover those entirely reliant on untaxed benefits or undeclared income. For example, the total population also includes individuals which do not interact with the tax system including 300,000 persons under 15 years of age and around 80,000 unemployed. Unlike most survey data, tax record data have limited demographic data, such as educational attainment. It also does not include all benefit data such as direct transfers such as child benefit transfers. In addition, while the tax records are based on the gross incomes of taxpayers, survey data are typically based on an equivalisation of the disposable incomes of households, which reduces comparability.

¹⁶ Since no such cut-off threshold is used for other variables, the average of these variables may appear relatively lower than gross income.

Tax coverage of microdata

278. While microdata total PIT and SSC for 2015 and 2016 are broadly similar to official tax revenues reported by the Ministry of Finance of Slovenia (2018), it is important to note that they do not match exactly for a number of reasons. For example, it is not possible to identify part-time employment in the microdata, and where the tax rules differ, it is not always possible to distinguish who is receiving certain income.

Table A.1. Tax revenue coverage of microdata

PIT and SSC totals (EUR millions), 2015 and 2016

| | Financial Administration Microdata | | Ministry of Finance | |
|--------------|------------------------------------|-------|---------------------|-------|
| | 2015 | 2016 | 2015 | 2016 |
| PIT | 1,785 | 1,899 | 1,986 | 2,079 |
| SSC Employee | 3,072 | 3,190 | 2,893 | 3,020 |
| SSC Employer | 2,590 | 2,685 | 2,125 | 2,233 |

Total income by income category

279. **In Slovenia, there are six categories of income:** employment, business, agriculture, rental, capital (interest, dividends and capital gains) and other income. According to the microdata for 2016, Slovenia earns over EUR 21.2 billion in incomes, of which EUR 19.7 billion or over 90% is employment income. These are largely salaries (64% of total income) and pensions (21%). Income from business, agriculture, rental and capital comprise 2.7%, 0.5%, 1.8% and 1.4% of total income respectively.

Table A.2. Average and total incomes, by income type

Based on 1,498,185 taxpayers 2016

| | Mean (EUR) | Total (EUR millions) | % |
|--------------------|------------|----------------------|-------|
| Gross | 14,196 | 21,268 | 100% |
| <i>of which:</i> | | | |
| Employment | 13,176 | 19,740 | 92.8% |
| <i>of which:</i> | | | |
| Salary | 9,098 | 13,631 | 64.1% |
| Pension | 2,921 | 4,377 | 20.6% |
| Other Employment | 1,157 | 1,733 | 8.1% |
| Business | 387 | 579 | 2.7% |
| <i>of which:</i> | | | |
| Actual Cost Regime | 277 | 415 | 2.0% |
| Flat Rate Regime | 110 | 164 | 0.8% |
| Agricultural | 69 | 103 | 0.5% |
| Rental Property | 144 | 216 | 1.0% |
| Other | 112 | 168 | 0.8% |

Taxpayer classifications

280. **Taxpayers can derive income from multiple sources sometimes at the same time.** For the purposes of the microdata analysis, taxpayers are defined and classified into three mutually exclusive groups as follows: pensioners, self-employed and employees. A stylised illustration of the groups is shown in Figure 1.

- First, pensioners are defined as taxpayers with *any* pension income (even where they have additional employment or self-employment income).
- Second, the self-employed are defined as taxpayers that have no pension income but have a self-employment income which is at least 15% of salary and self-employment income combined. The purpose of this definition is to capture those taxpayers with significant self-employment activity.
- Third, employees are defined as taxpayers with a salary income and no pension income. Taxpayers that have predominately a salary income but also a small self-employment income (up to 15% of salary and self-employment income combined) are also classified as employees. In this way, when taxpayers have both employment and self-employed income, they are assigned to one group based on the extent of their self-employment income. By construction then, those defined as employees or the self-employed do not have any pension income.

Figure A.1. Stylised illustration of taxpayer groups, 2016

Note: Circle sizes are stylised and do not correspond to taxpayer numbers. Numbers rounded to nearest thousand for illustration.

Source: Authors' calculations based on Ministry of Finance of Slovenia tax records microdata.

281. **For each category, a stricter definition can be applied** to include only those taxpayers that exclusively derive their income from that category (i.e. 100% of their income). For simplicity, these are referred to as 'full' employees, self-employed and pensioners.¹⁷

¹⁷ For the self-employed this would include only those taxpayers with 100% self-employment income (and no pension or employment income), for employees only those taxpayers with 100% salary income (and no business or pension income)¹⁷ and for pensioners only those with 100% pension income (and no employment or self-employment income). These groups are loosely referred to as pure pensioners, pure self-employed and pure employees.

282. **The Table A.3 shows taxpayer numbers for the total and full groups in 2016.** In 2016, there are approximately 742,000 employees, 584,000 pensioners and 69,000 self-employed. Together, the three groups represent a comprehensive picture of the taxpayer population – they account for over 93% of taxpayers and 98% of gross income. Taxpayers not included are, for example, those who exclusively derive income from capital, agriculture, rent or ‘other employment’ (all groups also have some mix of additional income from such sources).

Table A.3. Number of Taxpayers, by Group 2016

| Group | Total Taxpayers (A) | ‘Full’ Taxpayers (B) | (A) / (B) |
|------------------|---------------------|----------------------|-----------|
| 1. Employees | 741,670 | 725,655 | 98% |
| 2. Self-Employed | 69,000 | 56,234 | 81% |
| 3. Pensioners | 583,530 | 537,182 | 92% |

Methodology of the costing of the main recommendations

283. **This report produces various simulations to estimate the potential impacts of tax rate changes and base broadenings in Slovenia.** The analysis is based on all 741,670 employees for 2016 in the microdata (with the exception of the allowances simulation which includes all taxpayers).

284. **The analysis begins by simulating reductions in the employee SSC rate.** It then extends this by simulating PIT rate increases across the first four brackets and a reduction in the top PIT rate - for both a cut in employee SSCs and not. Next, the PIT implications of a base broadening measure are provided where tax allowances are reduced from 5% to 25%. In addition, an estimate of the SSC loss from capping employee SSCs is provided.

285. **The broad approach taken has been to reduce the reported employee SSC on the tax records and to substitute this into an estimate of taxable income** – income from employment less employee SSC less allowances. Conceptually, both reduced employee SSCs or allowances will increase taxable income for all employees and will push some employees into higher PIT rate bracket. Consequently, the 2018 PIT schedule is reapplied retrospectively to the 2016 tax record data and new PIT brackets and PIT are estimated for each employee. Given this framework, PIT rate increases can be readily applied to newly estimated levels of taxable income. Similarly, reduced levels of allowances reported on the tax records can be readily substituted into the taxable income estimate. An evaluation of these estimated variables confirm that they provide reasonable estimators – estimated taxable income and estimated PIT are within EUR 1,000 and EUR 500 of actual reported amounts respectively for 90% of employees.

286. **To simulate the impact of reduced employee SSC rates on overall SSC and PIT revenues, three methodological steps are undertaken as follows.**

- First, the employee SSC amount on the tax records is assumed to be 22.1% of employment income for all employees. This assumption allows for applying a

range of reduced employee SSC rates which are associated with reduced SSC amounts for each employee.

- Second, a new taxable income variable is defined and estimated as income from employment less employee SSCs and less allowances. Given these re-estimated variables, it is possible to simulate new levels of taxable income for each employee by substituting the reduced SSC employee amounts into estimated taxable income. Conceptually, reduced employee SSCs increase taxable income and push some employees into higher PIT rate bracket.
- Consequently, given new levels of taxable income, PIT must also be re-estimated for each employee using the PIT rate schedule. To do this, the latest 2018 schedule is applied retrospectively to the 2016 tax record data. An evaluation of these estimated variables confirm that they provide reasonable estimators – estimated taxable income and estimated PIT are within EUR 1,000 and EUR 500 of actual reported amounts respectively for 90% of employees. The estimated PIT, with employee SSC set at the current 22.1%, is used as the comparison counterfactual for the simulated reforms.

287. **Finally, two caveats are important.** First, the analysis assumes no behavioural change and linearity. Second, while the microdata PIT and SSCs are broadly similar to total tax revenues reported by the Ministry of Finance of Slovenia, they do differ for various methodological reasons.
